Posological Tables of the British Pharmacopœia for 1898.—This useful little book compares the doses and strengths of official substances as given in the Pharmacopœia for 1898 with those given in that of 1885. It is published by Messrs. Jewsbury and Brown of Manchester, who will forward a copy to any medical man if he will apply to them for one.

JOURNALS.

Journal of the Sanitary Institute. Vol. XIX. Part II. July, 1898. London: Edward Stanford. Price 2*s*. 6*d*.—The "Purification of Water for Barrack Prisons and other Institutions" is the title of Lieutenant-Colonel Lane Notter's (R.A.M.C.) paper which was read at the sessional meeting in February. The question is approached with a view rather to the conditions which obtain in India and other places abroad than to those which prevail in this country. The proposal to render water sterile by the addition of bromine or calcium hypochlorite, though apparently effective, is hardly one which will commend itself to people accustomed to English methods. Still, under certain circumstances abroad, it might find its uses. Dr. C. Childs's paper on Water-borne Enteric Fever gave rise to a discussion at the Institute which was raised to a good level by a letter to the chairman from Dr. Sims Woodhead, who drew attention to the great importance of ensuring the purity of the soil through which water-mains and pipes are carried. The volume contains other papers and notices of interest.

THE LANCET.

LONDON: SATURDAY, AUGUST 13, 1898.

AFTER a chequered career, full of startling episodes and reversals, the Vaccination Bill becomes virtually the Vaccination Act. In Parliament the hottest of the contest centred round the conscientious objector. First of all the Bill contained no conscience clause; then in the second reading debate Mr. CHAPLIN for the Government declared that he would resist to the death any such clause. In the Grand Committee he successfully maintained this attitude for a time and defeated by a very narrow majority Sir WALTER FOSTER'S amendment to the contrary. Later, however, Sir WILLIAM PRIESTLEY defeated Mr. CHAPLIN in so far as to obtain the acceptance of conscientious objection at four years of age as a substitute for a second penalty. In the House of Commons the Government once more, through the mouth of Mr. CHAPLIN, announced that it would never consent to recognise the conscientious objector; then, through the mouth of Mr. BALFOUR, it did consent and itself introduced and carried a clause. Next, on the third reading, it adhered to its new view and refused to recommit the Bill for the purpose of deletion of the Clause. "In another place," however, the Lords spiritual and temporal overcame the Government after a very close fight and expunged the added clause. In the Commons it was once more inserted and on the return of the Bill to the Lords they agreed by a majority of 55 to 45 to let the Government and the Commons have their way.

It is a curious point that some of those who, like Lord SALISBURY, fought most strenuously on behalf of the conscientious objector indicated at the same time that they entertained serious doubts as to his very existence, conscience in their opinion having little or nothing to do with the matter. Even a misnomer, however, is more convenient than no name at all, and to have given him his rightful title would have made his defence more difficult to those who felt it their political duty to defend him. While, therefore, they grumbled over the term "conscientious objector" they had not the courage to substitute the word "faddist" or to define the conscience clause as a clause for the relief of cranks. Not that we ourselves have objected to the recognition of the existence of anti-vaccination cranks. On the contrary, we have held that it is the duty of Parliament to look plain facts in the face, one of these facts being the increase in many parts of the country of the numbers of these cranks and of their evil influence on the general community. In our view, indeed, the "conscience clause" is to be regarded as a kind of asylum for the reception of such persons and for the prevention, so far as may be, of the injury which they are otherwise capable of doing to the public. Their posings as village HAMPDENS, their dearly loved imprisonments, and presentations, their processions, and brass bands, and baitings of auctioneers engaged in the disposal of impounded goods must now in great measure be given up. They themselves testify how loth they are to part with these delights and how anxious to retain some fragment of them. Regarding the passing of the conscience clause the official organ of the Anti-Vaccination League eagerly urges that "it by no means ends our struggle. It still remains true that a man must waste a day's work and expose himself to trouble and probably to insult at the hands of some ignorant upstart on the bench if he wishes to keep his children's blood unpolluted," and it vows that "there shall no court adjudicate on our conscience in respect to our children." If this means anything it means that there will now be refusal alike to procure the vaccination of the child and to take the steps provided for avoiding penalties for non-vaccination. In that event the law will take its course and refusal to pay a penalty will be followed by seizure of goods or imprisonment. But is the League quite sure in its own mind that seizure of goods and imprisonment will have the same desired results under the new system as under the old? Will it be possible to rouse the same prejudice and passion over JOHN SMITH'S refusal to go before a court in order to state his objections to vaccination as could be roused when JOHN was able to allege that he was suffering martyrdom in order to "keep his children's blood unpolluted"? We hardly think so; but it will certainly be interesting to watch during the five years to which the operations of the new Act are limited the struggles of the League to keep alive its hitherto comparatively easily maintained agitation.

For us the main feature of the later proceedings of Parliament regarding the Bill is the important statement by Lord LISTER, confirmed for the Government by Lord HARRIS, that we may expect a Revaccination Bill to be introduced next session. For the public weal this is, indeed, good news and in our estimation it should go far to allay the anxiety which the medical profession naturally feels as to the likely recrudescence of small-pox in this country as a result of neglected infantile vaccination. That Bill will be awaited with the greatest interest and will be heartily welcomed in so far as it makes a serious attempt to establish a national system of revaccination. It may be hoped that the Bill will not concern itself with revaccination alone, but will contain some of the more important of the other provisions which have been urged on the Government by the medical profession, but which have not found a place in the present measure.

One of the most satisfactory side-results of the introduction and discussion of the Government Bill in the session which is just closing is the elicitation of a huge body of usually silent public opinion regarding the value and essential importance of vaccination. In Parliament Mr. CHAPLIN complained that it was only anti-vaccination that gave voice to itself until his proposal for a conscience clause roused the other side into speech. So it has been in the country in connexion with the merits of vaccination itself. So long as the public believed that vaccination was in no danger they treated with sovereign contempt the orations and newspaper letters of the anti-vaccination crusaders, but when once they came to suppose that there was some sort of danger that under Government auspices vaccination might fall

Digitized by Google

into desuetude they spoke out in quite an unmistakable fashion—in a fashion, indeed, which has no doubt had a very considerable share in inducing the Government to promise the legislation for revaccination which the profession has demanded so earnestly and up till now so unavailingly. If the introduction of the conscience clause has done nothing else it has done immense good not only in opening the way to revaccination, but in influencing the Government to step forward into the excellent path of duty thus opened before them. May their progress therein be unfaltering and persevering until the desired goal be attained.

THE Americans have been most successful in their war with Spain so far as any actual fighting has had to be done. The enterprise, audacity, and skill displayed by their naval service have been unmistakeable and attended with remarkably successful results, even if it has to be admitted that the Spaniards at sea have always been overmatched and their naval commanders have exhibited a lamentable want of those strategical and tactical qualities which certainly might have made their fleet most embarrassing, if not formidable and dangerous, to their American enemy. Great pluck and courage in facing defeat and death they have, however, undoubtedly displayed. The American troops have also shown, as might have been anticipated, of what splendid fighting material they are composed. But, despite the brilliant results at Cavite and Santiago and the dramatic successes hitherto attained by the American forces, there will be great rejoicing in the United States when peace with Spain has become absolutely assured and when the existing state of anxious tension is relieved in regard to the deplorable condition of General SHAFTER'S force in Cuba and the numerous outbreaks of typhoid fever elsewhere in the camps of the United States army.

We do not take any special credit for having from the very first dwelt upon the probability that the real enemies—more deadly than the soldiers of Spain—would turn out to be malaria, typhoid fever, yellow fever, and dysentery, for this was generally recognised. It has been the experience of most expeditions undertaken under similar conditions, even if the lamentable medical history of the Spanish losses of recent years in Cuba had not told the same story and clearly indicated the same moral. In spite of the firm belief that war was bound to occur with Spain on account of Cuba, which must have been long present in the minds of the Government and people of the United States, it found them quite unprepared when it did come—at least, as far as the land forces were concerned. Even if Spain has accepted the proffered terms of peace without any reservations the political and military difficulties which still remain to be settled are very great; but the serious health condition of the American army is now *the* emergent and pressing consideration. The troops in Cuba—at Santiago and in its vicinity—are, according to the official declaration of their generals and officers, in a deplorable condition. General SHAFTER'S report of July 6th states that the sick on that day numbered 3681, including 2638 fever cases, of which 421 were fresh cases. The number of men who returned to duty was 477. The deaths numbered seven, none of them being due to yellow fever, but on the 7th these numbered eleven, of which five were due to yellow fever. The American troops disembarked in Cuba were fine fighting material and full of enthusiasm, but they had to begin their campaign at the commencement of the unhealthy season; they had heavy marches and hard fighting in an excessively hot, enervating, and malarious climate; they were badly equipped; they had no change of clothing and no shelter during the campaign; the weather was very wet and stormy; they were rationed on bread, meat, and coffee, the provisions were probably mostly tinned or preserved, and what fresh meat was procurable was necessarily tough and innutritious. The men were greatly fatigued and exhausted by their work and hardships in the field and their want of rest and sleep. The outcome of all this was, as might have been confidently expected, harvested as soon as the excitement was over and nervous exhaustion began to follow. At least 75 per cent., it is alleged, contracted malarial fever, from which recovery is very slow. It is easy to understand that the troops were consequently in a state to contract any disease but in no condition to withstand any such attacks, especially those of yellow fever or dysentery. Very little is said of the field hospital service accompanying the troops or of their medical supplies, but from the nature of an expedition of this kind, with rapid marches in a difficult country, it is scarcely likely that these supplies were provided on a scale adequate to the requirements of the force or that, if such were the case, they could have accompanied it where the transport of ammunition, commissariat and other stores must have been most difficult. What now remains to be done is to remove as soon as possible the present force, exhausted by the effects of their campaign and enervated by malaria, from Cuba to well-selected positions in America and to replace it by fresh troops from the United States. The shipping transport to be employed for this purpose should be capable of affording ample accommodation and be well provided in every respect with everything needful for the physically enfeebled and fever-stricken soldiers, together with ample supplies of quinine and good fluid nourishment of all kinds suitable to men under such circumstances. The troops sent to replace those removed should be composed of strong, healthy, and matured men suitably equipped for the climate and service; everything should be prepared beforehand for their reception at Santiago and along the marching route, with rest-camps at intervals so that they can reach their destination leisurely and without undue fatigue.

The lessons to be learned from the breakdown of General SHAFTER'S force briefly comprise, in other words, the duties of a country to its army and of the medical service to the soldiers under their charge. Under any circumstances an expedition to such a climate—the soldiers being young and unacclimatised men unaccustomed to campaigning and newly arrived in a hot, malarious and insanitary country—must be prepared to encounter serious risks to health, but these may be in a large degree discounted by forethought in the provision and settling of all the requisite hygienic details

Digitized by Google

beforehand. Time is here an important element of course. There is no royal road to the end in view. England, France, and other countries have had to learn by bitter experience that every sanitary detail has to be carefully thought out and, as far as practicable, provided for in view of escaping disastrous consequences. The nature of the climate and its diseases, the choice of the best season for military operations, the selection of the force, the food, the clothing, the best times for marches, and many other matters of military hygiene have obviously to be all most carefully considered. On all these points it falls within the province of the medical service to furnish their recommendations and suggestions for the information of the War Office and military officials, and we can only assume that this was done. General SHAFTER, it is alleged, blames the medical department and declares that it did not make adequate provision for the needs of the army and refuses to accept any responsibility for shortcomings attributable to the Surgeon-General and his service. The Surgeon-General, on the other hand, according to the special correspondent of the *Times*, has issued a printed statement in defence of his department and blames the service in control of the transport. The matter, which is a very serious one, calls for further investigation, which it will most certainly receive. Meanwhile the people of the United States are an eminently energetic, practical people, and we may be quite sure that they will recognise and do their very best to remedy any difficulties or defects which can be overcome. Everything points to the Americans having in future to make a large increase in their fleet and army of regulars and their medical services.

THE output of new synthetic remedies is becoming colossal—there is no other word for it—and so intimate a knowledge is the chemist gaining of the structure of compounds that it appears to be only necessary to indicate to him the kind of compound wanted when he immediately produces it in the form probably of a crystalline powder. Indeed, it is the rapid realisation of stereo-chemistry or structural chemistry which is largely responsible for the great number of complex compounds which the synthetic chemist is continually bringing before the notice of the profession in the form of new remedies. It is pretty safe to say that in general they are coal-tar derivatives, offspring of the benzene nucleus, belonging to the aromatic series or closed chain compounds. We have little to urge against the marvellous ingenuity of the modern chemist in thus elaborating an almost endless series of compounds which with few exceptions, be it remarked, are invariably tendered as belonging to one of three classes of drugs—namely, antiseptics, antipyretics, and analgesics. Nor would we belittle the importance of these synthetic processes considered as triumphs of our knowledge of architectural chemistry for we cannot help bearing in mind the great number of valuable additions to pharmacology which have thus been made. We need not give examples; they occur again and again in the new Pharmacopœia (1898).

One point, however, which to our mind is of the utmost importance in relation to the progress of therapeutics deserves at this juncture to be brought into notice. It is this. The rapid and apparently endless production of new synthetic compounds is such as to leave little or no time to determine their real pharmacology. No sooner is a substance discovered than it is put upon the market as a new remedy, an analgesic, antipyretic or hypnotic; it is soon superseded by another which is claimed to have a more reliable and more satisfactory effect. Well may the practitioner stand aghast, for no time is left to study the relation of the structure of the new compounds in regard to their precise therapeutic effects. And thus many of the so-called new remedies are administered blindly, sometimes with good effects, sometimes with an indifferent action and sometimes with bad sequelæ. Now from the point of view of the chemistry of compounds and more particularly their structure in relation to their action on the system this is distinctly retrograde. In other words, this multiplicity of organic compounds bewilders the physician, and, what is worse, tends to take him back to pure empiricism. There can be little doubt that a knowledge of the physical properties of the chemical composition and structure of substances will eventually enable us, if we pursue the study intelligently, to predict the nature and extent of the value of a substance in treatment—i.e., as a drug. We possess already sure and certain evidence that this may be so. The action of certain drugs, it is well known, may be so modified by the introduction of a new molecule as not only to lose their original properties but actually to become pharmacologically active in the reverse direction. It is upon this basis that there is promise of much progress being made in pharmacology and in treatment by drugs. The subject has recently been touched upon in a masterly style by Mr. CHARLES SYMES, Ph.D., on the occasion of his presidential address at the opening of the British Pharmaceutical Conference in Belfast on the 9th inst. As he pointed out—and there is an excellent moral connected with the observation—most of the synthetic remedies are produced in Germany, where the manufacture has become an extensive chemical industry, for the simplest of all reasons, that in that country there are less restrictions on experimenting with animals than in this country; the chemist and physiologist work together, the one altering the molecules and molecular arrangement in the chemical substance, and the other testing most carefully the effects obtained thereby. In another part of his address, for an advance copy of which we are indebted to the courtesy of the editor of the *Pharmaceutical Journal*, he adds that the chemist is now the architect and builder, using certain atoms and molecules to build up chemical structures to meet the wants of the medical profession in the treatment of disease. That may be so, but is not the tendency thereby induced more on the side of empirical than of rational treatment? Some proof of this surely appears in a later and, we think, very trenchant remark, in which, after giving a list of many of the new synthetic remedies together with their formulæ and scientific names (which are generally very long, as, for example, benzoylmethyl-tetramethyl-γ-oxypiperidine-carbonic-methylester, this being the expressive name of eucaine, a comparatively new anæsthetic), he says of the fifty substances enumerated: "It will be noted that a large percentage possess antiseptic, antipyretic and analgesic properties; *so that their rapid growth would seem to be due more to commercial enterprise*

Digitized by Google

than to meeting a real want in medical practice." The italics are ours.

We appeal, therefore, for further research and more opportunities for such research, otherwise pharmacology will remain empirical instead of being based, as it should be, on the structure and constitution of bodies. If structure determines the action of a remedy, surely the only scientific course to pursue is to ascertain what are the exact changes which a modification in structure will produce. Then with the knowledge and skill of the chemist we may vary at will our remedy and so attain results in accordance with the necessities of the case. But with such an innumerable host of remedies announced as newly discovered substances day by day such a study is well-nigh impossible, at least if it is to keep pace with the number of compounds at present elaborated in this multiplex fashion.

Annotations.

"Ne quid nimis."

THE REPORT OF THE BOMBAY PLAGUE RESEARCH COMMITTEE.

WE have received a copy of the report of the Bombay Plague Research Committee which has recently been issued. Strictly speaking we ought to say that the report is only that of certain members of the committee—i.e., the reports of Surgeon-Major Lyons and of Surgeon-Captain L. F. Childe are given in full; of Mr. E. H. Hankin's report a summary only is given; and Dr. W. M. Haffkine has not yet arranged the material which he has collected in the form of a report. Surgeon-Major Lyons gives a very full account of the course and symptoms of an ordinary case of plague and in addition of the two "erratic" forms where, although most of the general features of acute plague were present, there was neither enlargement of the lymphatic glands during life nor was there found anything in these glands after death but slight enlargement and congestion. In one of these forms—septicæmic plague—the microbe grows in the blood; in the other it grows in the lungs, giving rise to primary plague pneumonia. The septicæmic form was very fatal and began with severe rigors; it was also characterised by severe nervous prostration and marked cerebral symptoms. The pneumonic form somewhat resembled an ordinary severe pneumonia except in three important points — firstly, the rusty sputum of ordinary pneumonia was absent; secondly, the pulse-rate in plague pneumonia became very frequent in direct ratio to the rate of the respirations; and thirdly, the physical signs were those of broncho-pneumonia rather than of lobar pneumonia. Plague in the pneumonic form is exceedingly difficult to diagnose in an early stage, and the importance of an early diagnosis is all the more to be insisted upon since the sputa from the first contain plague bacilli. In the Bombay epidemic no cases of glandular fever were met with. This disease has been considered as being plague and is characterised by the appearance of buboes with little or no constitutional disturbance. In Calcutta a number of cases have occurred, but up to the date of the report (November, 1897) no cases of true plague had occurred in that city. The treatment by antitoxin has not up to the present met with much success. Surgeon-Captain Childe deals with the macroscopic and microscopic pathology of plague together with the mode of exit and entrance of the plague bacillus from and into the body. It leaves the body by means of hæmorrhages or secretions which may contain blood—e.g., the urine. In the pneumonic type the bacillus is always present in the sputum. With regard to the mode of entry the bacillus generally finds admission through some slight lesion of the skin, it produces no local reaction at the seat of inoculation, and a bubo forms at the lymphatic gland nearest to the seat of inoculation in the direction of the lymph-stream. With regard to infection by food no evidence was found post mortem that the bacillus had entered by the stomach or intestines, but cases of cervical bubo might have resulted from infection through abrasions on the lips, tongue, or tonsils. The following is Surgeon-Captain Childe's account of a marked case of plague pneumonia:—

"The patient, a medical man, was in his usual health on Jan. 2nd and had a sudden rigor in the morning and felt fever coming on. During the day a bad headache developed, he felt nausea and vomited several times, and he had pains and a tired feeling in his limbs; his tongue remained clean and moist and his skin was slightly moist. At 2 P.M., temperature 103·4°, pulse 116, respiration 25, and there were but slight variations during the day. On Jan. 3rd had passed a bad night and felt worse, and all the symptoms persisted except the aching of the limbs, and he felt very ill. The temperature remained between 103·5° and 104·5°, pulse about 110, and respirations about 23 throughout the day. During the afternoon he felt some pain at the lower part of the left axilla just under the anterior fold, but there was no glandular enlargement or pain in the glands anywhere. On Jan. 4th had passed a bad night and felt very ill, temperature 104·6°, pulse 113, respiration 25, tongue still moist with a little fur behind, and no sordes about the lips or teeth; the other symptoms as before. During the night he began to cough and brought up some watery sero-mucous fluid, slightly blood-tinged, and the pain remained in the same place, only more diffused now, being felt over an area of a square inch. At this part some moist sounds could be heard like those of early pneumonia and they could also be heard just below the left clavicle; the rest of the lungs and other organs appeared to be normal, as did the lymphatic glands. Patient considered that he had pneumonia, but the symptoms were not like ordinary pneumonia.

"For the onset was different, the condition of the tongue and mouth different, there was no dyspnœa or pneumonic disproportion of pulse and respiration, and the sputum was not at all like rusty sputum, for it was loose and free, coming up with the slightest cough, it was watery, looking more like serum than mucus, and it was slightly pink, not rusty yellow at all. Also there was the striking fact that the patient's general condition was far worse than could be explained by the small amount of lung-disease present. So I examined the sputum under the microscope and found it full of bacilli looking like those of plague, and cultures were made from which a pure growth of the plague-bacillus was obtained. During 4th and 5th patient became steadily worse, his temperature remained about 104° and his expectoration became most profuse; the moist sounds were heard over a larger area as well as slightly at the bases; the respirations increased to 35 and then to 45 and the pulse to 120 and 135; and he ultimately died early on Jan. 6th."

The necropsy in another case showed patches of pneumonic consolidation together with general engorgement and œdema of the lungs. Mr. Hankin's report deals mainly with the best means of disinfection and he comes to the conclusion that the best disinfectant is a weakly acid solution of corrosive sublimate. The whole report is most interesting and shows a very large amount of work, most of which seems to have been done in the midst of very trying circumstances.

"A REASONABLE FAITH."

IN the *Victorian Independent*, an Australian paper, for June of this year appears a short paper by Dr. J. W. Springthorpe under the above title in which an attempt is made to give a rational basis of belief. A large number of medical men rank themselves as "Broad Churchmen"; their scientific

Digitized by Google

training is the obvious explanation of this, and Dr. Springthorpe enlarges on this theme. His language is rather terse but he is evidently a deep thinker and his views will probably be supported by many scientific men. He points out that "to thinking men and women the question of questions still remains the purport of life and the destiny of man, and upon this vital issue the science of to-day has, perhaps, arrived at three great generalisations. The first is the ultimate unity of origin of all forms of matter. Far out into the infinitudes of space stretches the impalpable luminiferous ether. Admit simply that atoms can be formed by different aggregations of its ever-moving mass and upon this almost immaterial basis we can build up the grandeur of universe." The writer then proceeds to the second point—namely, that modern science has practically proved that development is the law of life and that all forms of life have an ultimate unity of origin, and he even ventures the further suggestion that life itself may, after all, be simply a new kind of movement in molecules of a certain complexity. "But this tale of glorified matter is only half its story. For apart altogether from other arguments of weight it seems in ultimate ontology more rational to place mind behind all manifestations of matter than to regard thinking and purposive mind as evolved from insensate mass. Thus the necessary antecedent to, and correlative of, an infinite ether is an omnipresent Supreme Mind, of which, indeed, the ether perhaps may be simply the first manifestation or obverse side. The modern conception of religion thus claims to start with an omnipresent Supreme Mind." It is difficult in a short abstract to follow the whole of Dr. Springthorpe's arguments. He finally considers Christianity. "One came from the Supreme; taught that amidst His infinite attributes there is a divine humanity; proclaimed the Gospel of the Fatherhood of God and the brotherhood of man; and lived a life in perfect accord with the Supreme Will even to the death. This is the supreme fact that Christianity offers for the acceptance of the race." Then comes the point to which we have already referred, that "in its interpretations we have still to follow that evolution which is the law of our progression." It is mainly because there are in the orthodox pale so many outgrown forms and phrases and so little provision made for their own developmental needs that so large a proportion of the progressive minds of our time find themselves unable to ally themselves cordially with any special religious denomination.

INCREASE OF EOSINOPHILIC LEUCOCYTES IN TRICHINOSIS.

IN the *Journal of Experimental Medicine*, vol. iii., No. 3, 1898, Dr. Thomas R. Brown has published some important researches on the pathology of trichinosis. He finds that there are marked changes in the number and character of the leucocytes in the blood—leucocytosis with great relative increase in the number of eosinophilic cells. Normal blood contains about 6500 leucocytes per c.mm., of which 4810 (74 per cent.) should be polymorphonuclear neutrophiles and 130 (2 per cent.) eosinophiles. Ever since Ehrlich discovered the different affinities of the granules in the various kinds of leucocytes for acid basic and neutral dyes the numerical variations in disease, especially of the eosinophilic leucocytes, have been studied. A constant increase of the latter has been found in certain diseases—viz., leukæmia, bronchial asthma, pemphigus, prurigo, psoriasis, eczema, &c. The largest percentages hitherto reported are 22 in bronchial asthma, 33 in pemphigus, 24 in eczema, 27 in ankylostomiasis, and 21 in anterior poliomyelitis. In a case of trichinosis Dr. Brown observed that the number of leucocytes at different periods was 15,000, 20,000, 27,500, and 11,000 per c.mm. With this leucocytosis the percentage of eosinophilic cells showed enormous relative increases; thus they amounted at different times to 37, 10, and 15 per cent. of the total leucocytes and once they reached as high as 68·2 per cent. This relative increase of eosinophilic cells necessarily involved a relative decrease of the polymorphonuclear neutrophiles, which from 80·4 per cent. sank as low as 6·6. Further, in the muscles, especially in the degenerating areas, he found a hitherto undescribed condition—a large number of eosinophilic cells, which suggested that these cells might be phagocytic. From the constant inverse relationship between the eosinophile and the neutrophile cells and the similarity in size and character of their nuclei he infers that the former cells may arise from the latter. This change possibly took place in the muscle, for both kinds, as well as transitional forms, were there found. All these facts suggest the theory that the polymorphonuclear neutrophiles wander out of the vessels and act as phagocytes on the degenerated muscle and that in so doing they become transformed into eosinophile cells which, returning to the circulation, cause the marked increase of the latter. It is of interest that Kischensky has come to a similar conclusion regarding the origin of eosinophiles in the sputum of asthmatics. Dr. Brown thinks that the marked increase of the eosinophilic cells may prove of value in the diagnosis of trichinosis, indeed he found it so in two cases. But the whole subject of leucocytosis in disease is still in an elementary stage.

A SPANISH MEDICAL OFFICER'S EXPERIENCES IN CUBA.

DR. GONZALEZ GRANDA, medical officer of the first class in the Spanish army, has published some interesting observations in the *Revista de Sanidad Militar* of Feb. 1st, 1898, on the wounds and injuries which came under his notice during the first phase of the Cuban campaign. The cases noted are full of professional interest and the results achieved prove once more the immense value of antisepticism in the field. One soldier recovered after an exceptionally trying experience. During the engagement at Palma Soriano he sustained three severe sabre cuts, two dividing the parietal and temporal bones respectively and exposing the dura mater, whilst the third, impinging on his left shoulder, severed the upper half of the scapula. While under treatment the patient was attacked by yellow fever, but eventually he recovered and was sent to Santiago to be invalided. At Parana an officer was taken prisoner who had been hit by three Remington bullets. Two of the wounds were situated close to each other in the left shoulder running downwards and inwards and both of the projectiles had lodged in the thorax. There were severe cough, dyspnœa, and hæmoptysis. The third wound was superficial but of large size, being situated on the inner side of the left knee. Under the influence of ergotine, rest, tonic mixtures and antiseptic dressing the wounded man had recovered sufficiently in a few days to undertake a journey on horseback to San Luis. At Ramon de Guaninao a sharpshooter was wounded by an explosive bullet. The projectile entered beneath the right inguinal fold, causing comminuted fracture of the upper part of the femur. There were two apertures of exit, one longitudinal under the hip and the other star-shaped on the inner aspect of the thigh at the juncture of the upper and middle thirds. Under chloroform Dr. Granda, having opened up the wound, was able to extract seven pieces of bone as well as two strips of metal from the projectile. Recovery to a certain extent took place under antiseptics and a silicated bandage, but good bony union could not be secured owing to the excessive mobility of the short upper fragment. In conclusion, the Spanish surgeon formulates his observations as follows: (*a*) The projectiles used by the rebels were, in order of frequency, the ordinary Remington bullet, an explosive bullet, the

Digitized by Google

bullet used in the Mauser cartridge, and, finally, a repeating-rifle bullet. (*b*) Of all wounds the least dangerous were those caused by cold steel. Several moderately dangerous incised wounds are far graver than a single severe wound. (*c*) Of all gunshot wounds those due to the Mauser rifle were the least fatal. (*d*) The danger in a wound due to a Remington bullet depended chiefly on the range. Usually when a long bone was struck by a bullet the result was a comminuted fracture, but in many cases repeating-rifle bullets did not produce this effect; the leaden projectile, unenveloped by a metallic jacket, was easily deflected, causing damage to the soft parts alone. (*e*) The explosive bullets so freely employed by the rebels produced comminuted fractures of terrible extent, together with horrible crushing and laceration of the soft parts. These wounds are exceedingly grave "*quoad vitam et quoad functionem*." The range of an explosive bullet is short, but in the Cuban war this did not benefit the Spanish troops because the encounters always took the form of surprises or ambuscades, the shooting being invariably at close quarters.

BRITISH MEDICAL BENEVOLENT FUND.

IT is sad to find that the number of medical men who fail to secure any adequate income for their declining years is by no means small and that some at their death leave families quite unprovided for. Much, however, is done by the British Medical Benevolent Fund to relieve the hardships inevitable under such circumstances. The report of the committee for the year 1897 shows that the subscriptions and donations received during that period amounted to £1367, and that the sum paid out in grants was £1236, the grants ranging from £5 to £18, and being distributed to 167 applicants out of 216. Many of these cases had to be postponed from month to month for want of funds, and there was at the close of the year an unusually large number of very urgent cases waiting for relief. Besides the recipients of grants there were 107 annuitants who collectively received £2168, one of them being a widow who is sixty-one years of age and has eighteen children. The honorary financial secretary, to whom donations and subscriptions may be sent, is Dr. West, 15, Wimpole-street, W.

SIR HENRY ACLAND ON MEDICAL MISSIONS.

SIR HENRY ACLAND has published an Address on Medical Missions in their relation to Oxford. The address was delivered in December last to the Oxford University Junior Scientific Club. It shows that despite the imperfect health attaching to octogenarian years Sir Henry Acland still takes the greatest interest in movements which contemplate the well-being of the race and especially of such portions of it as are under the direct rule of Her Majesty Queen Victoria. The address was called forth by a letter from Sir T. Grainger Stewart, President of the old Medical Mission Institute of Edinburgh in connexion with the Edinburgh Medical Missionary Society, founded by the great Dr. Abercrombie. Sir T. Grainger Stewart describes its objects and dwells upon the efficiency of religious medical service as preparing the way for still more strictly religious work. He expresses the hope that the Universities of Oxford and Edinburgh might coöperate in this great work. The society aims at sending into the missionary field only men who have enjoyed the best medical and other training that Edinburgh can afford. There is a danger nowadays of fancying that a little smattering of medical and surgical knowledge in missionaries will enable them to meet their own wants and those of the people whom they seek to benefit. This conception has no encouragement from the Edinburgh Medical Missionary Society. Still less has it any favour in the address of Sir Henry Acland which carries the conception of the medical missionary further even than that of the Edinburgh Medical Missionary Society. He would embrace within its objects whatever will benefit men physically, socially, and morally. Medicine in its large sense—scientific, preventive, therapeutic, and administrative—has relation to all races, and to every individual. It has relation to education, and therefore, to some extent to the religious life of the individual and the community. The conditions of great cities, and in a less degree of rural communities, often incompatible with decency and even hotbeds of drunkenness and vice, are the chief care of medicine, which aims at their removal and their replacement by conditions favouring virtue and religion. Sir Henry Acland's enthusiasm waxes warmer and warmer, and carries him beyond the bounds of the objects of any mere church or denomination in his conception of the objects of Christian missions. "With the divisions of the Church of Christ medicine has nothing to do." Its essential services neither favour these divisions nor contemplate them, and we should gather from his address that he scarcely approves of medical institutions working as such for mere sectarian purposes. Undoubtedly, the rule in Edinburgh is to help only the education of medical students specially recommended by any Protestant body. Sir Henry Acland would have medicine bound by no such restrictions. He admits them to be natural in the present state of the world, but thinks them unnecessary. Nevertheless, he is practical enough to recognise the good done by those who are identified with particular churches and the burden of his address is to enlarge that good and to bring to the missionary service the very latest and the very best discoveries of medicine.

NERVE DISORDERS IN ZYMOTIC DISEASES.

Two cases illustrative of the nerve disorders which attend upon zymotic disease are described in the *Annales de Médecine et Chirurgie Infantiles* of Aug. 1st, 1898. The underlying fever in each case was measles. In both a maniacal delirium was the most marked symptom. This condition appeared in one case as a sequel on the twenty-first day of illness and was ushered in by mental depression and attended by hallucinations. This patient gradually recovered. In the other mental troubles appeared with the invasion of measles and were of similar character to those of the former case. With the appearance of rash, which was delayed till the ninth day, the nervous symptoms began to abate, but pneumonia supervened and proved fatal. The ages were thirteen and fourteen years respectively. If these data are worth anything—and they are supported by the experience of other observers — they teach the importance of the nervous element as a factor in the pathology and treatment of children's fevers. This is probably of more consequence at or about the period of puberty, though it can at no age be overlooked. It is likewise the more to be considered in connexion with cases of delayed or "suppressed" eruption. In its therapeutic aspect it must necessarily remind us of the paramount value of measures to hasten the appearance of the rash and frequently also of a judiciously sedative treatment.

THE SANITARY REDEMPTION OF HAVANA.

ONE good result which may be expected from the present war is that there will at least be a likelihood of yellow fever being stamped out in Cuba and of the town and harbour of Havana, the chief sources for spreading the infection, being thoroughly cleansed. The insanitary condition of Havana has been for many generations a serious menace to the health not only of the United States, but of all the trading nations of the world. Havana is the chief nursery of yellow fever and the principal centre for its dissemination to other

Digitized by Google

countries. According to a paper read by Dr. George Homan before the Medical Society of City Hospital Alumni of St. Louis a few weeks ago, "the harbour of Havana is a land-locked bay, deep, spacious and well sheltered on all sides. With the exception of some arms or inlets that reach in different directions the main bay or harbour proper may be likened roughly to a bottle or narrow jug with the neck set on the shoulders in an oblique direction. There are no streams of large size flowing into the bay, the Gulf tides are inconsiderable, the sewage and surface drainage of a large population have been poured for centuries into this almost stagnant basin, and with a temperature seldom falling below 70° F., the conditions afforded for breeding and storing disease are wellnigh perfect." As regards a remedy for this state of affairs it is, in the opinion of experts, but a question of a little engineering skill; in fact, it is declared by those in a position to speak with authority that by the application of certain sanitary measures Havana, from being one of the most unhealthy may be transformed into one of the healthiest cities in the world. Two means of effecting this desired change have been suggested, either that some method shall be devised whereby the waters of the bay will be regularly and frequently changed, or else that the pollution now poured into it shall be diverted and safely disposed of elsewhere. To effect the former it has been proposed to cut a canal leading from the bay to a point on the north coast with a view to establishing a current towards the Gulf. The other alternative is the diversion of the sewage now delivered into the bay and its disposal elsewhere without prejudice to public health. This would involve the construction of an intercepting sewer along the water front to receive the outfall of drains carrying domestic and manufacturing waste, and is a measure so commonly resorted to that no novelty presents itself in connexion with the suggestion. One thing seems assured, that be the difficulties in the way of the sanitary purification of Havana great or small, once the island is in the hands of the Americans their sanitarians will set themselves to the task of successfully solving the problem.

DEATH IN THE SWITCHBOARD.

ELECTRICAL fatalities are happily of rare occurrence, but when they do occur they are always of interest to the profession and the following account exhibits some unusual features. It appears that a student named Alker, aged twenty-one, with a surveyor and two firemen, went down No. 1 pit at the Park Colliery at Ashton, near Wigan. After they had descended they entered the underlooker's cabin, where a switchboard was placed with levers controlling certain electric circuits. When the party left the cabin the two firemen went first. The surveyor and Alker followed, the latter being behind. The surveyor happened to look back and then saw that Alker had hold of the switch near the door and seemed to be in pain. The thumb and one finger "were round the handle, whilst the other three fingers were on the brasswork of the board." The switch was put off by one of the firemen. Alker was caught in the act of falling and found to be dead. An electrical engineer gave evidence before the coroner as to the installation, which he said was working at a pressure of 500 volts and he stated that he did not consider such a pressure dangerous to life. It may be remembered that at the Board of Trade Conference some three years ago, upon the question of low-pressure supply, similar opinions were expressed. One gentleman said that he had felt no ill effect from a 600-volt shock. As a comment upon this there appeared at p. 1572 of THE LANCET, Dec. 21st, 1895, the following passage: "In view of the fact that so much depends upon contact and the manner of taking a shock, and that little or no information was given on this point, it is difficult to form any opinion from such a statement. Did the gentleman in question touch one pole only of a 600-volt circuit? If so, what was the earth insulation of the other pole? Was his body in contact with the earth? Or, presuming that he simultaneously placed one hand on each pole of the 600-volt circuit, what was the surface area of skin contact, and what the condition of the skin? ..... Had the surface area and condition of the skin been favourable for a low resistance contact, it is more than possible that the gentleman in question might ere this have been 'put to earth' in a sense other than an electrical one." These remarks seem to apply to the recent accident at Ashton. In the absence of more detailed information no definite opinion can be expressed. But suppose that the deceased, perhaps standing on damp ground and thereby making a good electrical contact with earth, touched with his hand one pole of a 500-volt continuous current circuit—if the other pole was earthed it is evident that a circuit might be completed through his body. It might be that the electric lighting was in conjunction with electric haulage. In such a case one pole would be earthed through the rails. Certainly under ordinary circumstances fatal accidents to human beings are not likely to happen with 500 volts, but the conditions necessary to bring about a fatal result are not at all improbable ones. Speaking broadly, it is of course correct to say that, other conditions being the same, a current is fatal in direct ratio with the electromotive force used; but these "other conditions" are second only in importance to the electromotive force itself. The contact area, the resistance of the body, the state of health of the person, and last, but not least, the duration of the shock, have all to be considered. It is not improbable that in a considerable proportion, perhaps in a large majority of cases, the fatality or otherwise chiefly depends upon the last named point. In the case under review it was with the hand closed upon the switch handle, and remaining so closed, that the shock was received. It is easy to see that the resistance of the body might be quickly broken down both by burning of the skin and by electrolytic action. Thus three of the chief factors in determining a fatal effect might here be present—viz., large contact area, low resistance of the body, and long duration of the contact. But what of the switchboard? Controlling switches such as would doubtless be used are usually of considerable size, then handles are either themselves non-conductors, such as wood, ebonite, &c., or if of metal are insulated so as to prevent current passing. If insulation of the handles breaks down the result would be the same as touching the terminals which may have been exposed. It seems probable that in the hurry to switch off and to catch up the other members of the party the deceased's hand may have slipped and touched the terminals near the handles. The accident is noteworthy, not because it throws any light upon the current that kills or because it enlightens the medical man as to the physiological mechanism of death by electricity, but because it drives home the familiar lesson that every electrical installation should be controlled by some device which may be absolutely relied upon to prevent accidental contact with a live wire.

POLLUTION OF THE MANCHESTER SHIP CANAL.

IT is a difficult task to free the Ship Canal from pollution, but the Mersey and Irwell Joint Committee persevere in their work and deserve much praise for their patient efforts in the direction of cleanliness and public health. The experts called in recently by the Manchester Corporation recommended the putting down of four small test filters and wished for a short time to investigate the results of th

Digitized by Google

treatment of the sewage by means of these filters, so that they will not be able to report to the corporation before the end of October. The corporation hope that this report when received will enable them to satisfy the Local Government Board that they can produce a pure effluent from artificial filters without having to buy additional land. If unsuccessful in this they will purchase the 200 acres required for treatment on the land which the Local Government Board has so far insisted on. The joint committee have therefore agreed to grant the corporation six months' further grace, and the summonses against the corporation have been adjourned for six months. About a month ago the Urmston and Flixton Joint Drainage Committee were summoned at the Manchester County Police-court for discharging untreated sewage into the Irwell and the Ship Canal on dates from June 15th to 29th. The joint drainage committee have a sewage farm and have allowed the farmer to take as long as he liked for cutting the grass and making it into hay, and while he was doing so the crude sewage was turned into the canal. Summonses were served on June 30th, but on July 4th the inspector found the same thing going on, and subsequently to this the local authority wrote to the Mersey and Irwell committee that they could not treat their sewage on the farm for six months, as the land was in the hands of contractors for the purpose of making additional works. Mr. Yates, the stipendiary, in the end fined the Urmston and Flixton authority, the imposed fines and costs amounting to £14 or £15, and advised them to apply to the joint committee for time in which to complete their works. Birch Park, perhaps the most beautiful of the Manchester parks, is traversed by a stream which should add to its beauties and attractions by the opportunities it gives for lake-like expansions and the ornamental cultivation of moisture-loving plants. But this brook, which sends its contribution of filth on towards the Ship Canal, has been a reproach and a by-word for years, and is, we may say, an ancient illustration of how Manchester sometimes, as in this case, allows an injurious and almost intolerably disgusting nuisance to remain unchecked. We should have supposed that every effort would have been made to prevent the air of this otherwise delightful recreation ground from being poisoned by the vile stench from this brook. In hot summer weather when the flow is diminished the nuisance becomes intensified. Perhaps the most promising way of obtaining its abatement would be to compel the Parks Committee to go under canvas on the banks of the brook for a few weeks every summer. Since the above was written the condition of the "Black Brook," as it is always called, came under the notice of the joint committee on the 8th inst., for which the corporation ought to be thankful. The pollution is said to be caused principally by drainage from houses and from a jam factory higher up the stream, within the district of the Reddish Urban District Council, who are to be informed that they must take immediate steps to stop the pollution or they will be proceeded against.

ARTIFICIAL ALBUMIN.

ALBUMIN has been described as being able alone, together with the water and salts invariably associated with it, to support the vital processes, and as the only alimentary substance which can do so. Its chemical composition is not a constant quantity, and its structure or constitution has been the subject of a great deal of speculation by physiologists. It must be accepted, at any rate, as a very complex body capable of being split up into several classes of substances. Thus the fact that it is able alone to sustain the vital processes is probably due to its being resolved or split up in the animal economy into nitrogenous waste substances, into fat and carbohydrates. This is why albumin can be substituted in nutrition for the fats and carbohydrates, but it is not adapted as an exclusive source of diet, since it presents material far in excess of the bodily needs, leading to considerable waste. A remarkable statement appeared in the daily press last week to the effect that albumin had been successfully "synthesised" by a professor at Vienna University from materials which would lead to the cheap production of albumin on a large scale. And so it has been assumed that the food problem will thus be solved. In the absence of further particulars it is difficult to set an exact estimate on the alleged discovery. If the synthesis of albumen has actually been accomplished that alone would be a fact of immense importance in physiological chemistry, but that such an accomplishment is going to revolutionise practical food questions no physiologist or sensible man will be prepared to accept in the slightest degree as probable. Pure albumin is already manufactured on a large scale and fairly cheaply too, and though the manufacture has been going on for years albumin pure and simple has not found any decided place in dietetics, nor has it been proposed to substitute it for ordinary articles of food. It is absurd to think that the time will come when we shall carry about a complete meal or dietetic outfit for the day in the shape of a thimbleful of powder. The animal economy requires other things and attributes besides the mere elements concerned in making good the waste of the tissues in the body. The importance of the discovery, however, if the announcement be correct, cannot be overrated as probably calculated to throw much valuable light on the processes of metabolism and nutrition.

INTESTINAL OBSTRUCTION BY ROUND WORMS.

THE well-known inconvenience and even danger arising from the presence of round worms in the alimentary canal receive additional confirmation from a case which is graphically described in the *Annales de Médecine et de Chirurgie Infantiles* of Aug. 1st, 1898. It is that of a child, aged nine years, who presented all the usual symptoms of intestinal obstruction with an area of dulness from 12 to 15 cm. in length, corresponding to an elongated swelling about the middle of the transverse colon. Laparotomy was performed and it was found that this swelling consisted of fæcal matter and that the colon at the junction of its left third with the other two-thirds was actually "corked" (*sic*) by a mass of cord-like substance which proved to be an entangled knot of round worms. Massage of the colon was successful in reducing the obstruction, the contents of which were pressed as far as possible towards the sigmoid flexure. The abdominal wound was then closed. The relief of symptoms was rapid and pronounced; on the third day, with the help of calomel and santonine, three round worms were passed by the anus and the child was well in a week.

AN Italian lady, Signorina Esther Bonomi, has obtained at the University of Genoa the first doctorate in medicine granted to a female student, in modern times at least, in Italy. Another lady, named Dr. Katharina van Tusschenbroek, has been appointed to the professorship of gynæcology in the University of Utrecht.

THE Home Secretary has appointed Dr. Thomas Morison Legge to the new post of Medical Inspector of Factories and Workshops. We congratulate Dr. Legge, who has done excellent work in public health and who was also Secretary of the recent Royal Commission on Tuberculosis, on his well-earned recognition.

MR. FRANCIS MARPLES, of Sheffield, has made a donation of £20,000 to the weekly board of the Royal Hospital of that city. In 1893 he presented to the Free Hospital for Children a sum of £27,000 on certain conditions, so that he has proved himself a really splendid benefactor of Sheffield medical charities.

WE may remind our readers that the Congress of the Royal Institute of Public Health will be held in Dublin from Aug. 18th to 23rd, 1898, under the presidency of Sir Charles Cameron. The honorary secretary of the Congress is Mr. Henry Campbell, Town Clerk.

IT is proposed to entertain Professor Virchow on the occasion of his forthcoming visit to England at a public dinner. Lord Lister, we understand, will take the chair and may count upon the support of the leaders of the profession.

A TELEGRAM to the Colonial Office received on the morning of Tuesday, August 9th, stated that no cases of plague had occurred in Hong-Kong last week.

THE REPORT OF THE SELECT COMMITTEE ON PETROLEUM.

THE Report of the Select Committee on Petroleum, a copy of which we received last week, is unquestionably a valuable document and contains, we venture to think, a most fair and comprehensive statement of the present position of the subject. The difficulties of legislation being directed in one way or another are carefully weighed, and it would be idle to deny that the conclusions express a perfectly impartial view of the case as they are the product of enormous labour, time, and thought. A perusal of the Report in one place would appear to carry conviction in one particular direction; at another it would appear to convey just the opposite conclusion. In a word, it is not difficult to see how sharply contention has waged round the main points at issue.

Our interest in the labours of this Committee has been centred in the one great question of the accidents arising from the domestic employment of paraffin lamps, and as our readers will recollect, we instituted a practical inquiry during the latter months of 1895, the results of which were published in THE LANCET of Jan. 4th, 1896, in the Report of THE LANCET Analytical and Sanitary Commission on Dangerous Paraffin Lamps. Our commission expressed the opinion that if legislation could be directed to the construction of lamps all that was needed to avert further dangers would be done. It was shown very distinctly that the chief source of danger arose from cheap lamps or from lamps of defective design and construction. The evidence of experience, it was pointed out, was quite in agreement with this conclusion, for the disasters that have been reported have been in almost every instance in the houses of poor families where the cheapest possible lamp was in use. There is no similar record of accidents published in the case of those who use lamps and can afford to pay a reasonable price for those of sound and safe construction. Yet the class just referred to are great patrons of the oil lamp using the ordinary oil of a flash-point of from 73° F. to 85° F. This difference may be due to the exercise of greater care and intelligence in the latter case. Against recklessness and carelessness no legislation is possible. THE LANCET Commission attributed most of the accidents to the leakage of oil through imperfect connexions and fittings, to the fragile character of the reservoirs, and to the oil becoming ignited on the lamp being upset. No satisfactory evidence could be obtained from the series of experiments made that a real explosion was a likely occurrence. Not in a single instance did an explosion result. The evidence placed before the Select Committee on Petroleum pointed distinctly to the same conclusion. Thus on page 15 of the Report occurs the following passage: "The Committee have received a large amount of evidence as to the special causes of lamp accidents. A large number of lamp accidents are reported as lamp explosions which it would appear from the evidence are not explosions at all. There is very weighty scientific evidence to the effect that actual explosions in lamps are extremely rare and that the conditions necessary to cause an explosion very seldom occur. It appears from this evidence that vapour when produced in a lamp is only in an explosive condition when mixed with atmospheric air in nearly the proportion of two parts vapour to ninety-eight parts air. It can then only explode if, through defects in the lamp, by blowing down the chimney, through an ill-filling wick or from some other cause, it comes into contact with the flame of the lamp. When the proportion of 2 per cent. of vapour increases, say, to 4 per cent., the mixture is no longer explosive. This is given as an explanation of the statement that explosions in petroleum spirit lamps are practically unknown as the vapour is generated so rapidly that the explosive point is past almost immediately the lamp is lighted." If this be so the possibilities of an explosion happening with high flash-point oil are greater than with the low flash-point oil.

Statements have been made from time to time in the newspapers that England was the dumping ground of the refuse oil of the United States, where, it was asserted, that legislation absolutely forbade its use. On page 13 of the Report of the Select Committee we read: "The Committee have taken a large amount of evidence as to the statement so frequently repeated that this country is made the sole market for oil of such a dangerous character as would not be allowed to be used in the United States or elsewhere, and have come to the conclusion that the statement is unfounded. Petroleum of 73° (Abel) is not only largely used in the United States but is chiefly exported to the principal European and Eastern countries." A more complete refutation of such statements could not have been made. We have not space to deal with the mass of material embodied in the report, but it is a satisfaction to us to find that many of the vital points contained in the conclusions of THE LANCET Commission were correct and in an exact line with the findings of a Parliamentary Committee which has been holding an inquiry extending over several years and which held fifty-three sittings and examined no less than eighty-five witnesses, the latter including scientific experts, traders in, and manufacturers of, both oil and lamps, and public officials. Nor were we alone in taking the view that the remedy lay in the State insisting upon a standard of construction for lamps instead of interfering with the present flash-point of the oil. "The evidence of this branch of the inquiry," it is stated in the Report, "is most conflicting and contradictory both as to the efficiency of the proposed remedy and as to what should be the particular flash-point if one should be adopted. Many witnesses contended that lamp accidents would be largely diminished, if not entirely prevented, by the prohibition of the sale or use of petroleum below a certain flash-point for illuminating purposes." On the other hand, "From the evidence before them by witnesses who have had long experience the Committee have come to the conclusion that lamps reasonably well constructed and used with a fair amount of care are safe with all ordinary oils."

After all the conclusions summarised in the Report are in the nature of a compromise, for the Committee recommend in paragraph 2 not only the adoption of a flash-point of 100° (Abel close test) as the dividing line between petroleum oil and petroleum spirit, but in Section 7 that statutory powers should be created to enable the Secretary of State to issue orders affecting the manufacture and sale of lamps, and lastly, in Paragraph 8, that information should be spread among the public as to the nature of petroleum and the management of lamps. The effect of legislation on the lines thus suggested cannot be predicted, and the validity of these conclusions can only be judged when we are in a position to turn to the evidence of experience. In conclusion we may repeat a remark which we made in an article upon the subject in THE LANCET of July 2nd, 1898, viz.—"if our attitude (that adopted in the report of THE LANCET Commission) should ultimately prove to be wrong we shall none the less welcome any alternative proposal, should it be followed by a happy issue, from whatever lines of reasoning it may have sprung. Let the flash-point be raised by all means if that will protect life and limb, and if at the same time it will not engender other hardships in the every-day conduct of human affairs."

A NEW SANITARY SERVICE AT BORDEAUX.

(FROM A SPECIAL CORRESPONDENT.)

THE town of Bordeaux has established a new system of sanitary control which seems likely to pave the way to a very great improvement in the condition of that important city. What is called the service of *l'inspection technique de la salubrité* was founded in 1897 by the new municipality elected in 1896. There was formerly a *médecin inspecteur de la salubrité*. He had no office at the town hall. His mission was to examine unhealthy districts, badly kept streets, and general causes of insalubrity. He was also the inspector of unwholesome industries. This function has now been suppressed and replaced by the *adjoint à l'hygiène* of the mayor, who must be a medical man, and by the new "technical service of salubrity" which must be under the direction of a sanitary engineer. The *adjoint* or substitute of the mayor thought it was necessary that he should be assisted by a technician knowing the detail of sanitary appliances, the cost of sanitary apparatus, the value of new patents, processes, &c. Hence the service of technical inspectors was organised. Its duties extend over many questions which were not included in the attributes of the *médecin inspecteur de la salubrite*. Apart from watching the causes of ill-health and inspecting unwholesome industries, which were the duties of the former medical inspector, the new service has organised an elaborate system of inspection over private dwellings. Throughout France there exists in all important centres an official "commission on unwholesome dwellings." But at present this commission only interferes when the householder will not carry out the improvements which have been suggested to him. If a complaint is made concerning the sanitary defects of some dwelling it is sent to the new service, which at once makes a report, indicates to the proprietor of the house in question what alterations are necessary and generally these suggestions are carried out. It is only in the event of refusal on the part of the proprietor that the matter is handed over to the "commission on unwholesome dwellings." This commission generally prescribes the same or similar remedies, and the measures thus recommended can then be presented to the municipal council. If they are approved by the council—and this is generally the case—then the proposed remedies can be enforced by law. Should the proprietor still refuse to comply he falls under the law of April, 1850, and a penalty can be inflicted. Unfortunately this penalty consists only of a fine, there is no power by which the sanitary improvements can be carried out in spite of the householder or proprietor. Therefore if the fine inflicted is less than the cost of the proposed improvements the house-owner pays the fine and the matter is allowed to drop. A project of law is now under consideration by which when such sanitary measures are approved by the municipal council the mayor will have the right to carry out the works himself and recover the costs from the proprietor by summary proceedings. In consequence of the arrangement just described the number of cases referred to the "commission on unwholesome dwellings" has been very much reduced, and this is only fair, as the members of that commission are not paid for the work which they perform.

Then there are many causes of complaint which come under the existing laws and it is not necessary to refer to the "commission on unwholesome dwellings" to have them rectified. Thus, for instance, if there is a heap of manure or there are some poultry in a backyard the police inspector can at once interfere. The "commission on unwholesome dwellings" has now therefore only to attend to cases where a recalcitrant house-owner refuses to comply with instructions given him or when some very serious measure is proposed such as the total evacuation and demolition of dwelling-houses. Then when sanitary works have been ordered there must be an inspector capable of seeing that they are properly carried out. With a service technically competent many questions which would lead to much debate and dispute can be settled at once.

Apart from the houses which already exist there is the question of the new houses which it is proposed to build. The plan of all new structures has to be sent to the town hall. These plans were formerly examined so as to see that the new building should be in harmony with the street and its surroundings, but no note was taken as to what would be its probable sanitary condition. Thus it sometimes happened that two or three years after a house had been built it was condemned by the "commission on unwholesome dwellings." It is true that the law of 1852 says that plans of proposed buildings shall be examined from the health point of view but the law does not state who shall be held responsible for the accomplishment of this duty. Therefore what was no one's business was never done; besides, there was no recognised authority technically capable of carrying out this clause of the law. The creation of the new technical service of sanitary inspection provides the machinery by which this long dormant law can at last be enforced. The plans for new buildings are now examined from the sanitary as well as from other points of view.

Another important duty devolving on the new sanitary service is the control of the emptying of cesspools. The company which has contracted with the municipality to do this work is bound by a set of regulations drawn up and accepted in 1874. But it was very urgent that there should be municipal officials ever on the watch to see that these regulations were strictly enforced. Then it is not only necessary that a cesspool should be properly emptied: it must be carefully examined to see that it is thoroughly water-tight. When a cesspool is reported to be leaking an inspector is sent from the town hall to verify the fact. When only solid matter is drawn out of a cesspool it is evident that the liquids have escaped. The inspector indicates what repairs must be done, and when they are completed the cesspool is closed in the presence of the inspector. He then affixes the municipal seal on the cement. Otherwise some householder would be tempted to reopen the cesspool so as to damage the walls and render them porous. The liquids would then escape and a long time would elapse before he would have to incur the expense of having the cesspool emptied again. At Bordeaux this is a particularly expensive operation. It used to cost nine francs per cubic metre, but now the charge has been reduced to six or seven francs. There is a project under consideration for the drainage of the town, and if this is carried out all the cesspools will be abolished. But a vast and costly scheme of this description is not likely to be promptly realised. Therefore it is very important that, in the meantime, the nuisance due to the cesspool system should be reduced to a minimum. Fortunately, in many parts of Bordeaux the landlords are as anxious as the municipality that their cesspools should be water-tight. In these districts the cesspools are below the underground water-level; therefore if they were not water-tight they would drain the surrounding subsoil, fill rapidly, and have to be constantly emptied.

The new technical sanitary service has under its charge the management of the municipal disinfecting station. This has been admirably organised. In a spacious, well-aired building there is a very large Geneste and Herscher stove. It measures 1·90 metres in diameter and 4 metres in length. Of course, the side for the admission of the infected linen, &c., is completely walled-off and separated from the side where the linen is taken out of the stove. The disinfectors wear a sort of uniform consisting of white overalls and a cap with hood covering the back of the neck. When they have placed everything in the stove they take off their uniform and put it in also. After this a side door admits them to a bathroom and disinfecting room where they change their other clothes and wash thoroughly. A very effective check is kept over each operation. On a printed formula the blank spaces are filled in and indicate accurately what has been placed in the stove, where it came from, and the nature and result of the illness of the patient. Attached to the disinfecting stove there is a registering thermometer. The slip of paper fastened to the drum of the thermometer bears the same date and number as the formula containing the list of the objects to be disinfected. The drum revolves by clockwork and on the paper is inscribed minute by minute the temperature prevailing in the stove during the operation. The two sheets are then pinned together. If any question arises or complaint is made these two documents are produced and it is at once seen to what temperature the objects have been exposed and for how long. By this means, also, it is easy to verify if the steam under pressure has been occasionally let off and the pressure reduced. If this is not done there is always the danger that a layer of compressed and cooler air will form within the stove and unless this is broken up by a sudden change of the surrounding pressure the same amount of heat will not

Digitized by Google

be evenly distributed over all the objects to be disinfected and the operation may not prove entirely successful. The clockwork thermometer is therefore a very practical and necessary adjunct to a stove for disinfecting by steam under pressure. The disinfecting is done gratuitously for the poor and a moderate charge is made where the persons concerned can afford to pay. A great many private families send things to be disinfected and sometimes even when this is in no wise necessary. Thus the bedding, &c., of a person who had died from diabetes were sent to be disinfected. The practice of disinfecting for cases of phthisis is also much on the increase, and as these patients often live a considerable time disinfecting for them brings in a small regular income. The *Mont de Piété*, or State pawning establishment, has likewise entered upon a contract with the municipality by which it pays £60 a year to have all the bedding pledged disinfected before it is stored away. Hopes are entertained that a by-law will be enacted at no distant date by which all auctioneers will be compelled to have all bedding disinfected before they take it to public sale-rooms. As it is, some auctioneers have already taken time by the forelock and voluntarily bring the bedding they have to sell to be disinfected. Of course they do not fail to boast of the precaution they have taken, produce the municipal certificate of disinfection and charge a heavier price accordingly. The public has, on its side, the intelligence to appreciate this proceeding and is willing to pay more for greater security. From these various sources, the income derived for disinfecting during the first month of this new service amounted to £28, so that the cost the municipality has incurred is likely to be covered by the receipts.

Cheap lodging-houses are under the supervision of the police; but now when the police are asked to authorise the opening of such a house they first consult the sanitary technical service. It is only when the recommendations made by this service have been carried out that the police authorise the taking in of lodgers. Unfortunately there is no precise law on this subject. The custom is to insist that there should be 20 cubic metres of space per head per night, but the whole matter is left to the discretion of the local authorities. A Common Lodging-houses Act, similar to Lord Shaftesbury's Act of 1851, is much needed in France. If Zola or Daudet could have written a novel something like Dickens's "Bleak House" such an Act might now be in force among our neighbours.

The new "technical sanitary service" has also to control all subsidised localities—such as theatres, *crèches*, schools, &c. In these establishments it insists on greater cleanliness than has as yet been observed; the walls are more frequently whitewashed and the drains more carefully looked after. The new service has likewise to report on all sanitary questions interesting the municipality, and for this purpose occasionally deputes a delegate to attend sanitary congresses and to visit foreign towns.

Somewhat after the model of what is being done for the Paris Municipality by Dr. A. J. Martin and M. Masson the Bordeaux "technical sanitary service" is seeking to establish a sanitary record for every house in the town. Some confusion has arisen as to what this means. The danger is that a house once visited and reported upon may be considered as having obtained a sanitary certificate and this may lead to a false sense of security. The persons employed to make these inspections are municipal agents or beadles. They are called *appariteurs* and their function is to report all defects in the public services. If the dust is not satisfactorily removed, the street is insufficiently watered, or any by-law is not properly carried out, complaint must be made to the *appariteurs* of the district. These men have no special knowledge of sanitary questions, but they have an intimate practical knowledge of the district in which they work, and some of them have worked in the same district for more than ten years. Bordeaux is divided into twelve districts. There are two *appariteurs* for each district and they are expected to inspect two houses per day. 2000 houses have already been inspected. There are about 36,000 houses in Bordeaux, so that it is anticipated that the work will be completed in some two years time. It is urged that these men, though not technically instructed in matters appertaining to sanitary engineering, are quite competent to answer the questions put down on a printed formula which they have to fill up whenever they visit a house. They must state when the house was built, what is its size, its frontage on the street its depth; the size and number of gardens or courts, the state of the soil, their ground level as compared with that of the street; what trades, shops, or businesses are carried on; the stables, their number, and the number of horses contained; the number of separate tenements, on what floor they are situated, whether they give on to the street or on to a court or garden, whence they derive their air supply and the number of inhabitants. These questions complete the first or white folio that has to be filled up. The second or pink folio deals with the sanitary conditions of the house. It is first necessary to state whether the house receives the town water supply, whether the supply is direct or whether there are cisterns, whether there is a meter and if so the duration of the subscription. Secondly, and in case the house does not receive the town supply, it is necessary to state at what distance is the nearest public fountain, whether there are any wells, where these are placed, what use is made of them, whether the waters have been analysed, and what decision was taken in consequence of such analysis. Then it is necessary to state how many closets there are in the house, whether they are private or used by more than one family, where they are placed, what is the nature of the seats and basins, the water-supply, the flushing apparatus; the soil-pipes, their situation, nature and condition; the ventilators, their origin and dimensions; the cesspools, whether water-tight, automatic or moveable, or whether the closets drain direct into the sewers. The methods of draining off the slop and rain-water have likewise to be described, and an account has to be given of the stables, the animals living in the house, and the manure heaps that may be on the premises. On the back of this sheet there is a space where diverse causes of insalubrity may be more fully detailed, together with the measures of improvement prescribed, and finally there is space for a record of what has been done as the result of these recommendations. The third folio is blue and deals only with lodgings recognised as insanitary and serves to tabulate the improvements ordered and the consequence of such action. The fourth folio is yellow and deals only with infectious diseases, the nature of such diseases, the date at which they were notified, the methods of disinfection employed, the death or otherwise of the patient. A fifth and green folio is devoted exclusively and in more detail to the disinfecting operations. All these five sheets are pinned together in a stiff wrapper but are sufficiently small to be carried about and filled up on the spot. It is maintained that when the above questions have been fully answered a very complete record of the house has been obtained. Such a record is not a certificate of efficient sanitation, but it is a basis on which further inquiry may be made when the occasion arises. By giving a different colour to the folios, according to the subject with which they deal, a question is quickly answered not only with regard to one house but with regard to a whole series of houses. With such a record at their disposal it will be much easier for the sanitary authorities to connect the outbreak of epidemics with the internal conditions of the dwellings concerned. The sanitary history of each house will thus be gradually built up and its value as a sanitary dwelling ascertained. The advantage of employing the *appariteurs* for this service is that they know every one. It is their business to distribute the voting cards to all the electors. They attend to all questions relating to water-supply, complaints as to the condition of the streets, the tables of cafés encroaching upon the causeway, dust removal, the numbering of houses, the registering of horses for the military reserve, the dog tax, accidents, flower-pots falling into the street, &c.; in a word, the *apparitour* is the man who always *appears* when anything goes wrong. From the sanitary point of view the great advantage rests in the fact that he is the representative of the mayor, and, therefore, carries the tricolor scarf and the silver medal with him. On an emergency he can put on these insignia of office and then he has the right of entrance both day and night into private houses as well as into public places. Sanitary inspectors have no such right for they are not recognised as agents of the law.

The new technical sanitary service has also to look after the disposal of house refuse. This is placed in boxes which are put out into the streets at night and collected in carts in the early morning. The carts are taken to the banks of the Garonne and emptied at a spot which is comparatively isolated though not far from the centre of the town. The carts are ranged in order on a landing stage

Digitized by Google

and tilted up so as to be emptied into barges below. There is also an embankment where other carts empty into railway trucks beneath. As the contents are raked out of the carts and pushed so that they fall into the trucks or the barges the men pick out the hard core, which they place in bags or hampers, and it is used for road-mending, &c. The soft core is then conveyed either by rail or by boats to agricultural districts where it is readily disposed of as manure.

Such are the principal functions of the "service of technical sanitary inspection" recently established at Bordeaux. Much of this organisation is due to the ingenious conceptions and activity of Monsieur E. d'Esménard, civil engineer and founder of the Society of the Sanitary Engineers and Architects of France. It may be remembered that in July, 1895, THE LANCET gave at some considerable length an account of a Congress on Hygiene held by this society at Paris. M. d'Esménard was the general secretary of this congress and it seems that the discussions which he was instrumental in bringing about have borne fruit. In any case the town of Bordeaux may be congratulated upon having taken an important step in the right direction and in having appointed M. d'Esménard as the chief of its "service of technical sanitary inspection."

LORD LISTER ON THE VACCINATION QUESTION.

THERE can be no doubt that Lord Lister's words upon the Vaccination Bill were awaited with much attention by the country and that his opinion has been an important factor in the passage of the Bill through the House of Lords under circumstances that are familiar to all our readers. We reproduce Lord Lister's speech in full that medical men may see exactly why the representative of medicine in the House of Lords voted as he did. Details of the different debates will be found in the columns usually devoted to Parliamentary proceedings.

Happily, said Lord Lister, it is not necessary to advocate the cause of vaccination. The great majority of the Members of the House of Commons—and I trust every Member of your Lordships' House—are aware of the enormous benefits which vaccination confers. The only question is, What are the best means of promoting vaccination in the country? It is to be observed that if the amendment to omit the clause is passed the result will not be the passing of the Bill without the clause objected to. The Bill will inevitably be sent back to us from the Commons with that clause re-introduced and the consequence will be that the Bill will be thrown out for the session. Not only so, but I am given to understand that if this Bill, which is framed very much on the lines of the Report of the Royal Commission, is thrown out this year it is not likely that the Government will introduce another Bill next session dealing with the subject, and very probably not in the year after, nor perhaps for many years to come. Therefore what we have to consider is whether it is better for us to pass this Bill in the form in which it is sent to us from the Commons, or be content to let the subject of the administration of the vaccination laws remain in the position in which it is. After giving the subject the best consideration in my power, my impression is that it would be better to pass the Bill as it is sent to us than to have no Bill at all. If after the long labours of the Commission and the endeavours of the Government nothing whatever were done by Parliament in regard to vaccination I think the result would be to cast discredit upon the whole subject. It is not as if the present compulsory system were working well. The appalling fact is that at the present time about one-third of all the infants born in England and Wales are at present not vaccinated. It is also true that nearly one-quarter of all the guardians throughout the country fail to put the vaccination laws into operation. This is a highly unsatisfactory state of things and it is undoubtedly the result of the anti-vaccination crusade. The anti-vaccinationist has two weapons. One of these is the supposed possible dangers of vaccination and the other is the martyrdom which it is thought is endured by persons who are subjected to fines and imprisonment for disobeying a law which, rightly or wrongly, they believe subjects their children to danger. Now, as regards the former of these weapons—the supposed dangers of vaccination—the glycerinated calf lymph will remove it. With arm-to-arm vaccination the danger does exist, though a very very remote one, of introducing into a child the terrible contamination of syphilis. Now, this danger is absolutely done away with by the use of calf lymph, since syphilis cannot occur in the calf. Then, the introduction of tubercle by vaccination is equally prevented by the use of the new lymph. Tubercle can, indeed, affect the cow, and, though very rarely, the calf; but it has been found that if tubercle bacilli are actually mingled with the glycerinated lymph in the course of a time far short of that at which the lymph would be issued for use the bacilli have lost their vitality. There remains the possible danger of communicating erysipelas. This cannot be done by the lymph as such, for the microbes which are the essence of erysipelas are as effectually disposed of by the glycerine as are the microbes of tubercle. But there is the possibility of the communication of erysipelas to the incisions made in vaccinating, just as there is the possibility of communicating it to any scratch or sore in a human being. That is a possibility, and it would undoubtedly be diminished by having the children vaccinated at home as is proposed in this Bill, instead of having them crowded together at the vaccination stations. But I trust that before very long any possibility of the communication of erysipelas by subsequent contamination will be done away with. The medical officers of the Local Government Board have now under consideration what would be the best, simplest, and most effectual means of using antiseptic measures for the treatment of the scratches—measures which will be simple and efficacious from the antiseptic point of view, and, on the other hand, not interfering with the efficacy of the lymph. I feel certain that the thing can be done. In the medical journals papers have been published by gentlemen who show that they have used antiseptic measures with perfect success in regard to vaccination. When this is accomplished there will be absolutely no objection to the vaccination of children on the ground of possible danger. But the conviction of the absolute safety of the process will take a long time to establish itself in the country. At the present time there is a deep-rooted idea, derived from the propaganda of the anti-vaccinationists, that serious danger exists; and it will take a long time before that idea is dissipated. The second weapon of the anti-vaccinationist—namely, the martyrdom of the honest objector—would of course be struck out of his hand at one stroke by the present Bill. It has been said that this conscience clause introduces a new and dangerous principle into our legislation. It may be so; but when I see that such a conscience clause was unanimously recommended by the eminent men who constituted the Royal Commission, including so distinguished a lawyer as Lord Herschell, I feel that I am free to consider this proposal on its merits otherwise. What is likely to be the effect of the Bill if passed into law? On this point we find the utmost discordance of opinion among medical men themselves. Some feel sure that the result will be an enormous diminution of vaccination throughout the country and a consequent increase of small-pox. Other men of high position and large experience in sanitary matters are equally confident that the Bill would greatly increase the amount of vaccination. As to which of these opinions is really correct I confess that I am hardly prepared to give an opinion. Those who hope good from the passing of the Bill think that when the conscientious objector has been so amply provided for, the guardians who now object to enforce the vaccination law will not hesitate to prosecute persons who, from mere idleness and without any real objections, neglect to have their children vaccinated. That this hope is not altogether without foundation we have a good illustration in a letter which appeared in the *Times* the day before yesterday from Sir Walter Foster. I will read to the House an extract from this letter—

In 1897 the Barton Regis Board of Guardians, in face of difficulties in enforcing the vaccination laws, adopted (of course without legal sanction) the recommendation of the Royal Commission. They informed the parents who had not submitted their children for vaccination that they (the guardians) would not proceed against them for default if a declaration of conscientious objection was made before a magistrate. In the Barton Regis Union in the last half of 1897 there was a population of over 200,000, and the number of births was 2,944. The defaulting parents were 350, and the actual number of declarations 130. Major Rumsey, the ex-chairman of the board, writes me:—

"The number of declarations (130) bore about the same proportion to the defaulters as the prosecutions under the Vaccination Acts did prior to the form of statutory declaration being adopted. The Barton

Digitized by Google

Regis Guardians (44) were nearly equally divided in opinion upon the vaccination question, but from the time of the adoption of the declaration the anti-vaccinationists offered no objection to the prosecution of those who did not furnish a declaration and a most disturbing element to the harmonious working of the board was removed. I may add that, had not the statutory declaration been adopted, a resolution would have been passed refusing to order prosecutions, and so the whole 350 would have escaped vaccination in place of the 130 referred to, the remaining 220 having no objection to vaccination, but being simply negligent or careless and requiring pressure."

In other words, the announcement of the remission of penalties for those who made a declaration of conscientious objection, together with the threat of their enforcement for others, induced nearly two-thirds of the whole number of defaulting parents to submit their children to vaccination. So far as one case can go, this seems to me most encouraging. It is to be observed that this Bill by no means entirely does away with compulsion, though it is commonly spoken of as if it did so. Those parents who refuse to make a declaration of conscientious objection before the magistrate may be fined or imprisoned as under the existing law for not having their children vaccinated; but, beyond that, the fact that the parent is obliged to appear before the justices is a mild form of compulsion. It gives the parent trouble and it will be a question with him whether it is more trouble to go before the magistrates or to have his child vaccinated under the very much less troublesome form provided under this Bill—namely, having it done by the vaccinator at the man's own house. If it turns out that the results are not so satisfactory as regards the behaviour of the guardians as may be hoped, it would be very easy by a simple Bill to arrange that the administration of the vaccination laws should be transferred from the guardians to the sanitary authorities, or at any rate to arrange that the vaccination officers shall have the expenses of prosecution which are now refused by the guardians paid to them either through compulsion of the guardians or by the State. Therefore I must confess that I am disposed to be hopeful as regards the effect the Bill in its present form is likely to have. But there is one serious omission from the Bill, and that is that it neglects to deal with revaccination. It is a matter of bitter disappointment to the medical profession of this country that revaccination is not dealt with by the Bill. The immense value of revaccination has been shown by the splendid results obtained from it in Germany, in the army, and more recently throughout the population. The value of revaccination is also indicated by the figures quoted by the Commission as to its effects in diminishing death from small-pox in our army and navy and postal service. The immunity of nurses in our small-pox hospitals, who are always revaccinated before admission as nurses, is another most striking proof of the efficacy of revaccination. The Royal College of Physicians of London have lately made the following declaration:—

> The Royal College of Physicians, having learnt that certain changes are likely to be made in the laws relating to vaccination, think it their duty to reiterate their conviction that vaccination, properly performed and *duly repeated*, is the only known preventive of small-pox.

In the *Times* this morning there is published a declaration of the Royal College of Surgeons of England, in which the following passage occurs:—

> We are, moreover, firmly convinced that revaccination is an additional safeguard and should be universally practised.

It is true that several members of the Commission considered that compulsory revaccination was so surrounded with difficulties that they were not able to recommend it, but two of the most influential members of the Commission, Sir William Guyer Hunter and Mr. Jonathan Hutchinson, thought that in spite of those difficulties revaccination ought to be made compulsory. And those Commissioners who were of the opposite opinion made this significant declaration:—

> Again, it is impossible to leave out of sight the effect that such an extension of the present compulsory law might have in intensifying hostility where it at present exists and even in extending its area, though if our recommendations, especially that which exempts from penalty those who honestly object to the practice, were adopted, this objection would be much diminished.

In the present temper of the House of Commons and of the country it would indeed be hopeless to attempt to introduce compulsory revaccination on the lines on which infant vaccination is now compulsory. But the conscience clause of the present Bill opens the door for very valuable legislation on this subject. It could be arranged, with a little assistance from the Education Department, that every master or mistress of a school where children of the age of ten years attend should keep a list of the names and addresses of those who had reached that age. Then the vaccinator could look in from time to time, at whatever periods it might be thought desirable, to see from the mere inspection of the arms of the children, which of them had not been recently vaccinated and the parents of these would be dealt with as this Bill proposes to deal with parents who have neglected to have their infants vaccinated, including the offer of doing the operation at home. This would ensure the revaccination of the vast bulk of the population, except the children of the so-called conscientious objectors, who, under the new system, would, I believe, be a rapidly diminishing quantity. Another effect of this arrangement would be that many children who had not been vaccinated in infancy would be dealt with at the age of ten. Personally, I should like if the Bill could be withdrawn this year and brought in again next year with this question of revaccination attended to, and also some other matters which the Commission recommended, but which are not dealt with in this Bill. But I fear that is a hopeless suggestion. However, as regards revaccination, the members of the Government who have been approached on the subject have given us good reason to hope that a Bill dealing with revaccination may be brought in next session. Such a Bill would, I think, be sure to pass the House of Commons, the great majority of which, however they may differ on other questions, are at one as regards the importance of revaccination. The medical Members of Parliament are certainly at one on this point. The Bill would therefore readily pass, and by introducing it the Government would do untold benefit to the community. The confident hope that the Government will see their way to take this course next session makes me the more readily acquiesce in what I confess is a tremendous experiment.

ANNUAL REPORT OF THE METROPOLITAN ASYLUMS BOARD.

FIRST NOTICE.

IT cannot be said that year by year as we take up this report and read of the isolation accommodation of the county of London that the problems connected with the isolation of infectious disease seem nearer solution. Indeed, as we peruse its pages and discover the enormous provision which has already to be made we cannot help reflecting on what the future may bring forth. Suppose, for instance, that what may be called the public health conscience turns itself to deal seriously and adequately with such diseases as measles and whooping-cough, and suppose still further that it were to set itself the task of isolating in special hospitals persons whose sputum yielded on examination the tubercle bacillus. However, progress in this direction will at least be gradual and we shall have ample time, as step by step is taken, to reflect on the situation. It is, however, otherwise with another disease, namely, small-pox, and it may be, with the House of Commons in its present frame of mind *quâ* compulsory vaccination, that the near future may have in store for us a demand upon the isolation accommodation—not only of the metropolis but of the country as a whole—which the provision at present existing will be utterly inadequate to meet. So far we profess, in London at least, to provide accommodation for a relatively well *primarily* vaccinated people and we have already had indications of the difficulties of doing even this when a wave of small-pox of at all an epidemic type visits us. The tale which may be told in the future when a similar wave passes over a much less well vaccinated people may, however, be very different, and we could well understand it if the Metropolitan Asylums Board considered it a duty, both to the ratepayers and to the public health of the metropolis, to utter a solemn protest against this prospective sacrifice of human life and against this prospective increase of expenditure which is likely to occur unless some better provision is made for revaccination. It is satisfactory, however, to know that the Government intend to introduce a Revaccination Bill next session.

In the volume before us the Statistical Committee commence their report by a reference to the increased responsibility which during 1897 has been placed upon them in being constituted the authority for dealing with poor children suffering from contagious diseases of the eye and skin or who are suffering from physical, mental, or moral deficiency;

Digitized by Google

and as to their duties in this direction they will doubtless have more to tell us next year.

Coming now to infectious diseases we find that out of 45,417 cases notified during 1897 as many as 39,251 were eligible for admission to the managers' hospitals. Out of this total 58·5 per cent. were actually admitted, a percentage considerably in excess of that of any previous year. Up to about the middle of July all scarlet fever *applicants* were admitted, but from the middle of June to the middle of December a certain percentage of the applications had to be turned away.

Of the admissible cases of each of these diseases isolated by the Board there were actually admitted during the year 1897 of scarlet fever 66·99 per cent., of diphtheria 51·64 per cent., of enteric fever 30·36 per cent., and of typhus fever (4 cases only) 50 per cent. Spot maps are furnished with the report showing the distribution of each of these diseases during 1897, and it is of some interest to note that around none of the hospitals is there any such special incidence of any of the diseases isolated as has so often been the case with hospitals used for the isolation of small-pox. Why should we not around ordinary fever hospitals see some evidence of what is alleged by some to be maladministration? As regards the age and case distribution of scarlet fever and diphtheria the figures for the year show nothing new—i.e., two-thirds of the total cases were among children under ten years of age, scarlet fever being most prevalent at ages from five to ten and diphtheria at ages under five.

Now with regard to the fatality-rate of the several diseases admitted. The 15,115 scarlet fever cases yielded a fatality rate of 4·06 per cent. as against one of 4·2 per cent. in 1896, the rate amongst the males being as usual in excess of that amongst the females. The highest fatality-rate was amongst children under five years of age, the first and second years of life being the most dangerous periods. The figures relating to diphtheria are obviously of especial interest just now and it is most encouraging to find that the fatality-rate for 1896 was the *lowest on record*—i.e., 17·4 per cent., or 3·6 per cent. below that of 1896. The figures for the years 1888 to 1897 show that the maximum mortality occurs in the first two years of life, the minimum (3·84 per cent.) being reached at the age-period twenty to twenty-five. The fatality-rate amongst the 664 cases of enteric fever was 18·7 per cent., or 2·5 per cent. higher than in 1896,

There were but 70 cases of small-pox admitted either into the hospital ships or at South Wharf in 1897 and of this number 13 died. Amongst 53 vaccinated cases there were 5 deaths, none of persons under ten years of age. Amongst 4 cases having "no evidence as to cicatrices" there were 3 deaths, all of persons over ten, while of the 13 persons whose vaccination cicatrix was "absent" there were 5 deaths, 4 of which were of children under ten years of age. Of the 82 members of the staff—such as medical men, nurses, wardmaids, and laundrymaids—who were brought more or less in direct contact with infection not one contracted the disease, and the same remark has to be made as to 114 other members of the staff employed about the premises either permanently or temporarily. Of the 70 cases of small-pox above referred to 47 were, it appears, to be traced to a previous case of the disease which occurred on board a Peninsular and Oriental steamer, and which, it is presumed, was the indirect cause of conveying the disease to an unvaccinated child who was subsequently removed to the Camberwell Infirmary, where the disease was not recognised until this case had been instrumental in conveying the disease to others.

The cases of mistaken diagnosis which figure in the reports of the Asylum Board are always of interest and it must be said that the figures for 1897 are not as encouraging as we might have hoped with the clinical teaching now available at the fever hospitals. No less than 5·3 per cent. of the patients were, after admission, found not to be suffering from the diseases for which they were admitted. Of 466 cases certified as suffering from scarlet fever 62 had measles, 115 tonsillitis, and 66 "no obvious disease," while of 643 cases certified as diphtheria 31 had measles and 551 tonsillitis. Of 293 cases certified as enteric fever 4 had bronchitis and 61 lobar pneumonia. The most startling figures have, however, concern with small-pox, and we learn that of 121 cases certified as suffering from that disease and removed to the wharves for transmission to the hospital ships no fewer than 52, or 42·9 per cent. of the cases, were not small-pox. Fortunately the vast majority of these mistaken diagnoses were intercepted at the wharves and did not find their way to the ships. In connexion with the valuable ambulance work done by the Asylums Board it may be noted that within recent years three new ambulance stations have been opened. The Park Hospital began to receive patients on November 8th of last year and the Grove Hospital will add 520 beds to the accommodation available. It will then remain to complete the erection of the Southern Convalescent Hospital and the carrying out of certain works at two of the existing hospitals, when there will be provision for over 6000 fever and diphtheria cases exclusive of the 740 beds at the Gore Farm Hospital. In spite of all this the statistical committee observe almost in a tone of despair that although the accommodation has now reached a magnitude of which no one dreamt even as recently as five years ago, nevertheless, for the fifth year in succession it has failed to meet the demands made upon it. In the matter of the proportion of staff to patients we learn that in the acute hospitals the proportion ranged from one *nurse* to 3·0 patients at the Western Hospital to one to 4·0 at the North-Western Hospital, the total staff at the former hospital being one to 1·4 patients and at the latter one to 1·9 patients. In addition to their fever and small-pox hospital accommodation the managers now possess asylums and schools for 6097 imbeciles as well as the control of the training ship *Exmouth*.

In our next notice we propose to deal with the "Medical Supplement" of the report.

Public Health and Poor Law.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Stirling County District.—Dr. J. C. McVail has embodied in his current annual report an interesting and instructive paper on dairy sanitation, a paper which comes very opportunely with the recently published report of the Royal Commission on the Control of Tuberculosis. After setting forth succinctly the fundamental principles governing the prevalence of bovine tuberculosis he points out that the real question at issue is by what means the temperature of the byre is to be kept at about 60° F. (the temperature most conducive to a full flow of milk from a cow) and at the same time to prevent the air from becoming impure. This condition can, he observes, be satisfactorily procured only by means of artificial heating, and he proceeds to discuss how this may best be carried out. To apply to the case of cows the standard which in man necessitates 3000 cubic feet of air per hour is clearly impracticable, and it is estimated that even if the space per cow were as much as 1000 cubic feet the air would need to be changed no less than 16 times per hour, a state of affairs which would not be pleasant in practice. Coming, then, to what is practicable, Dr. McVail furnishes some diagrams prepared by Mr. James Chalmers showing how existing byres may be heated. In one instance in the case of an existing byre it is proposed to lay hot-water pipes beneath the cow's manger, the fresh heated air being admitted by a series of Tobin's tubes, there being also in a well-arranged place some means for extracting foul air through the roof. The cost of carrying out this proposal for a byre of 20 cows is estimated at about £40 and the cost of fuel for six months at about 12*s.* per cow. The heating of new byres is, as Dr. McVail remarks, a comparatively simple matter, as they can easily be constructed with a due regard to the necessities of the apparatus. The cows could be arranged to stand either face-to-face or tail-to-tail with, of course, a proper interval between them. Dr. McVail, while describing the methods of artificial heating, is careful to insist upon the fact that even without this much good may be done by adequate ventilation and proper lighting, and he urges on his readers the paramount importance of the greatest cleanliness in all operations connected with the drawing, storage, and sale of milk. The paper was written before the report of the Royal Commission was issued, but the advent of the report does but accentuate the value of the paper, inasmuch as it develops in detail some of the Commissioner's recommendations.

St. Olave's (Southwark) Sanitary District.—There is a large trade hereabouts in hides and skins and during 1897 Dr. W. A. Bond, the medical officer of health, was informed of 7 cases of anthrax which were admitted into Guy's Hospital; there was also a case of a somewhat doubtful nature. After

Digitized by Google

operation all the patients but one recovered. Of 11 cases of enteric fever notified in this district during 1897 one was attributed to the consumption of oysters at Southend.

Maidstone Urban Sanitary District.—The remarkable epidemic of enteric fever which occurred recently in this district seems to be passing away into history and yet the Local Government Board report of the public inquiry which was held into its origin has not yet been issued. It is to be regretted that it should be thus delayed. In his current annual report Mr. M. A. Adams, the medical officer of health of Maidstone, refers but briefly to the subject and we can well understand why this should be so. He gave most valuable assistance to the three inspectors who held the inquiry and doubtless a full account of his evidence will be forthcoming in their joint report. Mr. Adams tells us that in this outburst, which will probably figure in most works on hygiene as an instructive instance of water-borne enteric fever, there were 1888 cases notified, 859 of these being referred to East Maidstone and 1029 to West Maidstone. The fatality-rate in the former district was 5·93 per cent. and in the latter 7·68 per cent. There was a large number of deaths from diarrhœa at a time just antecedent to the outbreak and Mr. Adams regards these cases as having arisen from causes other than those to which autumnal diarrhœa is usually attributed.

Poplar Sanitary District.—A watercress-bed in this district has recently been receiving attention at the hands of Mr. R. M. Talbot, who after demonstrating that water taken therefrom was contaminated with sewage succeeded in persuading the owner to close the bed. In the consumption of watercress we have not, as Mr. Talbot observes, the protection which in the cases of many articles of food is afforded by boiling.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5742 births and 3932 deaths were registered during the week ending Aug. 6th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 14·7 to 17·2 per 1000, further rose last week to 18·3. In London the rate was 18·4 per 1000, while it averaged 18·2 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·2 in Brighton and in Huddersfield, 10·9 in Oldham, 11·9 in Burnley, and 12·0 in Hull; the highest rates were 23·9 in Sunderland, 24·2 in Plymouth, 24·4 in Liverpool, and 25·6 in Salford. The 3932 deaths in these towns included 794 which were referred to the principal zymotic diseases, against 487 and 572 in the two preceding weeks; of these, 574 resulted from diarrhœa, 71 from whooping-cough, 52 from diphtheria, 45 from measles, 29 from "fever" (principally enteric), and 23 from scarlet fever. No fatal case of any of these diseases occurred last week in Brighton, Burnley, or Huddersfield; in the other towns they caused the lowest death-rates in Halifax, Swansea, and Gateshead, and the highest rates in Portsmouth, Liverpool, Sheffield, and Plymouth. The greatest mortality from measles and from scarlet fever occurred in Plymouth; from whooping-cough in Sunderland and in Preston; and from diarrhœa in Portsmouth, Birmingham, Leicester, Liverpool, Salford, and Sheffield. The mortality from "fever" showed no marked excess in any of the large towns. The 52 deaths from diphtheria included 30 in London, 6 in Leeds, 5 in Birmingham, and 4 in West Ham. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and only one small-pox patient was under treatment in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, the 6th inst., was 2326, against 2314, 2355 and 2321, at the end of the three preceding weeks; 224 new cases were admitted during the week, against 265, 276, and 232, in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 148 and 173 in the two preceding weeks, further rose to 174 last week, but were 7 below the corrected average. The causes of 55, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Leeds, Hull, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·1 and 18·6 per 1000 in the two preceding weeks, rose again to 20·0 during the week ending August 6th, and exceeded by 1·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·4 in Leith and 16·7 in Dundee to 30·0 in Paisley and 34·0 in Greenock. The 604 deaths in these towns included 77 which were referred to diarrhœa, 30 to whooping-cough, 20 to measles, 4 to scarlet fever, 2 to diphtheria, and 1 to "fever." In all, 134 deaths resulted from these principal zymotic diseases, against 118 and 113 in the two preceding weeks. These 134 deaths were equal to an annual rate of 4·4 per 1000, which was 0·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The 77 fatal cases of diarrhœa showed a further increase upon the numbers recorded in recent weeks and included 45 in Glasgow, 7 in Paisley, and 6 in Dundee. The deaths referred to whooping-cough, which had been 29 and 20 in the two preceding weeks, rose again to 30 last week, of which 16 occurred in Glasgow, 5 in Edinburgh, and 5 in Aberdeen. The fatal cases of measles, which had been 19 and 25 in the two preceding weeks, declined again to 20 last week, of which 7 were recorded in Dundee, 5 in Glasgow, and 5 in Edinburgh. The 4 deaths from scarlet fever showed a further decline from recent weekly numbers and included 2 in Greenock. The 2 fatal cases of diphtheria occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 75 and 79 in the two preceding weeks, were again 79 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 25, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 18·5 to 23·9 per 1000, was again 23·9 during the week ending Aug. 6th. During the past four weeks the rate of mortality in the city has averaged 22·3 per 1000, the rate during the same period being 16·2 in London and 19·1 in Edinburgh. The 160 deaths registered in Dublin last week corresponded with the number in the preceding week, and included 27 which resulted from the principal zymotic diseases, against 12 and 14 in the two preceding weeks; of these, 18 were referred to diarrhœa, 5 to "fever," 2 to diphtheria, 1 to scarlet fever, but not one either to small-pox, or measles. These 27 deaths were equal to an annual rate of 4·0 per 1000, the zymotic death-rate during the same period being 3·7 in London and 2·8 in Edinburgh. The fatal cases of diarrhœa, which had been 4 and 9 in the two preceding weeks, further rose to 18 last week. The deaths referred to different forms of "fever" which had been 1 and 3 in the two preceding weeks, further rose to 5 last week. The mortality from scarlet fever and from diphtheria corresponded with that recorded in the preceding week. The 160 deaths in Dublin last week included 46 of infants under one year of age, and 31 of persons aged upwards of sixty years; the deaths of infants showed a marked increase, while those of elderly persons showed a decline upon the number in the preceding week. Two inquest cases and 2 deaths from violence were registered; and 55, or more than a third, of the deaths occurred in public institutions. The causes of 11, or nearly 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JULY, 1898.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during July in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·1 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 7·1, 7·2, and 7·1 per 1000 respectively. Among the various sanitary

areas the rates were considerably below the average in Kensington, Hampstead, St. Giles, St. Martin-in-the-Fields, Strand, Shoreditch, and Woolwich; while they showed the largest excess in Fulham, Clerkenwell, St. Saviour Southwark, St. George Southwark, Newington, St. Olave Southwark, and Bermondsey. Two cases of small-pox were notified in London during July, against 4, 1, and 6 in the three preceding months; these 2 cases occurred in Camberwell sanitary area. No small-pox patients were under treatment during the month in any of the Metropolitan Asylums Hospitals. The prevalence of scarlet fever in London during July showed a marked increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, St. George Hanover-square, St. Pancras, St. George Southwark, Newington, St. Olave Southwark, Bermondsey, and Plumstead. The Metropolitan Asylums Hospitals contained 2255 scarlet fever patients at the end of July, against 2270, 2147, and 2146 at the end of the three preceding months; the weekly admissions averaged 242, against 218, 223, and 208 in the three preceding months. The prevalence of diphtheria in London during July showed a slight further increase upon that recorded in recent months; this disease was proportionally most prevalent in Fulham, St. James Westminster, Clerkenwell, St. Luke, Poplar, Newington, Battersea, and Lewisham sanitary areas. There were 1014 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of July, against 923, 917, and 971 at the end of the three preceding months; the weekly admissions averaged 146, against 134 in each of the two preceding months. The prevalence of enteric fever in London showed a marked further increase upon that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Westminster, Hampstead, Hackney, and St. Saviour Southwark. The Metropolitan Asylums Hospitals contained 87 enteric fever patients at the end of July, against 59, 54, and 53 at the end of the three preceding months; the weekly admissions averaged 16, against 8 and 11 in the two preceding months. Erysipelas was proportionally most prevalent in Hackney, St. Giles, St. Olave Southwark, Rotherhithe, and Greenwich sanitary areas. The 17 cases of puerperal fever notified in London during July included 3 in St. Pancras, 2 in Paddington, 2 in Fulham, and 2 in Chelsea sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, July 30th, the deaths of 5083 persons belonging to London were registered, equal to an annual rate of 14·7 per 1000, against 18·1, 15·7, and 14·6 in the three preceding months. The lowest death-rates in the various sanitary areas were 7·8 in Hampstead, 11·0 in Woolwich, 11·2 in St. George Hanover-square, 11·5 in Wandsworth, 11·6 in Camberwell, 11·7 in Plumstead, and 11·8 in Paddington; the highest rates were 20·1 in Westminster, 20·2 in Strand, 20·6 in St. James Westminster, 21·1 in St. George-in-the-East and in St. George Southwark, 23·1 in Limehouse, and 24·2 in St. Olave Southwark. During the four weeks of July 698 deaths were referred to the principal zymotic diseases in London; of these, 281 resulted from diarrhœa, 150 from whooping-cough, 115 from diphtheria, 96 from measles, 31 from scarlet fever, 25 from enteric fever, and not one either from small-pox, typhus, or any ill-defined form of continued fever. These 698 deaths were equal to an annual rate of 2·0 per 1000; among the various sanitary areas the lowest zymotic death-rates were recorded in St. George Hanover-square, Hampstead, Stoke Newington, St. Giles, City of London, and Camberwell; and the highest rates in Clerkenwell, St. Luke, Shoreditch, St. George-in-the-East, Limehouse, Poplar, St. George Southwark, and Newington. The 281 fatal cases of diarrhœa were as many as 505 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Fulham, St. Luke, Shoreditch, St. George-in-the-East, and Newington sanitary areas. The 150 deaths referred to whooping-cough were 13 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Kensington, Clerkenwell, Limehouse, St. George Southwark, Bermondsey, and Lambeth. The 115 fatal cases of diphtheria were 42 below the corrected average number; this disease showed the highest proportional fatality in Paddington, Westminster, Clerkenwell, St. Luke, Shoreditch, Poplar, Lambeth, and Lewisham sanitary areas. The 96 deaths from measles were 131 below the corrected average number; among the various sanitary areas the mortality from this disease was highest in Clerkenwell, Whitechapel, Limehouse, Poplar, Bermondsey, and Rotherhithe. The 31 fatal cases of scarlet-fever were less than half the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 25 deaths referred to enteric fever were 9 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Lee. In conclusion, it may be stated that the aggregate mortality last month from these principal zymotic diseases was less than half the average, the deaths from each of the diseases being below the average.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was equal to 143 per 1000, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, Hampstead, Stoke Newington, St. Martin-in-the-Fields, St. Luke, and St. Olave Southwark; and the highest rates in Kensington, Fulham, Holborn, St. George-in-the-East, Limehouse, and St. George Southwark.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced:—Fleet-Surgeon Edward W. Luther to the *Thunderer*, additional for Pembroke Dockyard. Staff-Surgeon William M. Lory to the *Repulse*. Surgeon W. L. Martin to the *Vivid*.

ROYAL ARMY MEDICAL CORPS.

Colonel William A. Catherwood, to be Surgeon-General, vice J. W. Maxham, retired. The under-mentioned Captains to be Majors:—John S. Davidson, James Will, James Moir, James Fallon, John V. Salvage, Arthur R. Aldridge, Joseph Fayrer, Charles P. Walker, Charles J. MacDonald, Charles J. W. Tatham, Thomas H. T. Clarkson, Herbert W. Austin, Cathcart Garner, Robert W. Wright, Edwin Eckersley, Reginald J. C. Cottell, James R. Burrows, John Keatly, Daniel Hennessy, David M. Saunders, William Kiddle, Dennis M. O'Callaghan, Michael J. Whitty, Henry A. Cummins, James F. Donegan, John Donaldson, Hugh B. Mathias, George Bent, George H. Barefoot, Foster R. Newland, Reginald J. Windle, Robert J. D. Hall, Edward S. Marder, Charles W. Allport, John J. Russell, John S. Edye, George Scott, Thomas Browning, Andrew Hosie, George F. H. Marks, Ralph Holyoake, Robert N. Buist, John J. C. Watson, Thomas Du B. Whaite, Henry T. Knaggs, and Ferdinand S. Le Quesne, V.C. The following Lieutenants to be Captains: Lionel Fergus Smith, Robert J. Blackham, Septimus H. Fairrie, George T. K. Maurice, Rupert Fawssett, John V. Forrest, Henry W. Grattan, Francis E. Gunter, John H. Campbell, and John Grech. The under-mentioned surgeons on probation to be Lieutenants: William Henry Snyder Nickerson, George Snyder Nickerson, George Bedford Crisp, Robert Strickland Hannay Fuhr, Walter Jagger, Alexander Bremner MacCarthy, George Johnston Stoney Archer, Robert Selby, Sydney Octavius Hall, Alfred Edmond Weld, James Stuart Gallie, Francis Joseph Christopher Heffernan, Arthur Edward Thorp, Cecil Wilmot Mainprise, Henry Herrick, Edwin John Dobbin, James Cowan, Austin Romuald O'Flaherty, Henry Beckles Gall Walton, and Edmund Philip Hewitt.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain Thomson (Bombay) are replaced at the disposal of the military department. The services of Surgeon-Lieutenant-Colonel Macdonald (Bengal), Senior Medical Officer, Port Blair, are placed temporarily at the disposal of the military department. Surgeon-Major Hudson (Bengal) is appointed to officiate as Senior Medical Officer, Port Blair. The services of Surgeon-Captain Hall (Bengal) are placed temporarily at the disposal of the Chief Commissioner of Assam. The services of Surgeon-Captain Williams (Bengal) are replaced at the disposal of the Government of Burmah. Surgeon-Captain Moir, First Resident Surgeon, Presidency General Hospital, Calcutta, is allowed furlough for one year.

Digitized by Google

Surgeon-Captain O'Kinealy, Second Resident Surgeon, Presidency General Hospital, Calcutta, is appointed to act as First Resident Surgeon of that institution during the absence on leave of Surgeon-Captain Moir, or until further orders. Surgeon-Captain Oldham, Civil Surgeon of Backergunge, is appointed to act as Second Resident Surgeon, Presidency General Hospital, Calcutta, or until further orders. Surgeon-Lieutenant Sealy has been appointed Chief Medical Officer, Railway Inspection duty, Kalyan. Surgeon-Lieutenant-Colonel F. Street, D.S.O., and Surgeon-Captain J. B. Smith have respectively delivered over and received charge of the office of the Deputy Sanitary Commissioner, Central Registration District. To be Surgeon-Colonel: Brigade-Surgeon-Lieutenant-Colonel Arthur Mudge Branfoot, Madras Establishment. To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel Arthur Henry Cole Dane, M.D., Bombay Establishment.

VOLUNTEER CORPS.

Artillery: 1st Norfolk (Eastern Division, Royal Artillery): Surgeon-Lieutenant H. M. Evans to be Surgeon-Captain. *Rifle:* 2nd Volunteer Battalion the Northumberland Fusiliers: Surgeon-Major H. F. Hurst to be Surgeon-Lieutenant-Colonel. 1st Volunteer Battalion the Worcestershire Regiment: Surgeon-Captain A. R. Waddell resigns his commission. 1st Wiltshire: Brigade-Surgeon-Lieutenant-Colonel F. F. Lee resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement, vacating at the same time the appointment of Senior Medical Officer to the Western Counties Volunteer Infantry Brigade. 9th Lanarkshire: Surgeon-Lieutenant-Colonel J. Lindsay resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force: *North-Eastern District: Rifle:* 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant-Colonel Thomas Alexander McCullagh. *North-Western District: Rifle:* 2nd Volunteer Battalion the Lancashire Fusiliers: Surgeon-Lieutenant-Colonel Charles William Thorp. 2nd (Earl of Chester's) Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant-Colonel Alexander Hamilton. 6th Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant-Colonel Thomas Fort. 1st Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Surgeon-Lieutenant-Colonel James Charlesworth. *Scottish District: Artillery:* 1st Aberdeenshire Volunteer Artillery: Surgeon-Major Robert John Garden. *Rifle:* 3rd Lanarkshire Volunteer Rifle Corps: Surgeon-Lieutenant-Colonel Alexander Napier. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Major Sir James Reid, Bart., K.C.B. 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant-Colonel William Goldie Stevens and Surgeon-Lieutenant-Colonel Matthew Hamilton Taylor. *Southern District: Artillery:* 2nd Hampshire Volunteer Artillery (Southern Division, Royal Artillery): Surgeon-Lieutenant-Colonel Gordon Sparrow. *South-Eastern District: Rifle:* 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant Adolphus W. W. Caudle, retired. *Western District: Rifle:* 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Acting Surgeon Talfourd Jones, retired.

THE FOOT-GEAR OF INFANTRY SOLDIERS.

This important subject continues to excite attention among continental military and naval hygienists. In the course of a general report on his charge, Surgeon-Major Prat of the 1st Regiment of Marines, at present quartered at Cherbourg, devotes considerable space to a disquisition on the soldier's boot in ancient and modern times, showing conclusively by examples from Xenophon downwards how largely the fate of armies depends on their mobility and how entirely this depends upon an effective foot-gear. If his best is required of him a foot-soldier should be provided not only with a pair of boots which have been made to fit his individual foot, which are impermeable to dust and moisture though not to air, and which are constructed of the best and most durable material known to science tempered by experience, but also with a comfortable pair of shoes, likewise constructed from the best material, for him to rest his tired feet in at the end of the day's march. This principle is fully recognised and acted upon in the German and Austrian armies, but apparently the French Ministry of War has not yet gone beyond the stage of experiment. The boot of the French *fantassin*, according to the latest pattern, has no strap and is double soled, the inner sole being three millimetres thick and the outer four. In length the boot varies from 26 to 33 centimetres, and it is made in no fewer than 32 sizes. The reporter likewise reviews the question of socks, which it seems do not form part of the *fantassin's* regulation kit, although generally worn at his own expense. Viry in his *Principes d'Hygiène Militaire* recommends the "Russian sock," which consists of a cloth band wound round the foot and ankle, but unless very skilfully applied it is apt to ruck up and form creases. On the whole a woven or knitted sock is far preferable, provided its fit is accurate. In the English army, we are told, after an exhaustive trial unsewn or seamless socks were served out to the infantry, but for some unexplained reason the next issue was reduced by one-half to make way for socks with seams. Surgeon-Major Prat concludes this portion of his report with a very accurate description of an English pedestrian's running shoe of which he highly approves. In this connexion the following short extract from a paper on Naval Hygiene, by Principal Medical Officer Dr. Danguy des Desert, in the *Archives de Médecine Navale* for July may be worth quoting: "The sailor's footgear leaves much to be desired; the shape could not possibly be more unsightly or the construction more defective. The sewing is so coarse that it injures the foot, and the ends are so pointed that there is no room for the toes. It is made in four sizes only. Without asking for eight different lengths, with four separate sizes to each length, as in the English navy, I think our sailors may reasonably claim a better made boot, less weighty and not so clumsy. The article which they now receive is so heavy and so cumbersome that the men are for ever injuring themselves by slipping down the iron gangways, and whenever they can, even in the coldest weather, they prefer to go barefoot."

BRIGADE-SURGEON-LIEUTENANT COLONEL D. D. CUNNINGHAM, F.R.S., C.I.E.

The retirement of this officer has led the Government of India in the Home Department to address a very handsome and highly appreciatory letter to the Director-General of the Indian Medical Service in regard to the very eminent scientific services rendered by Brigade-Surgeon-Lieutenant Colonel Cunningham to the State. After setting forth a history of the valuable work performed by this officer over a number of years as Professor of Physiology at the Medical College, Calcutta, and as Special Assistant to the Sanitary Commission with the Government of India, together with a list of his various published researches and reports, some of which were in collaboration with the late Dr. Timothy Lewis, the Government of India finally add: "By the retirement of Dr. Cunningham the Government of India lose the services of one of the most distinguished of the scientific men who have served them, the Indian Medical Service one of its most eminent members, and yourself an invaluable adviser. He carries with him on his retirement the warmest thanks of the Government of India for his long and distinguished services." We may add that Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham has the reputation of being one of the most able, conscientious, and laborious workers not only in India but in the medical profession, and many of his scientific researches are of a very original kind and based upon honest and independent inquiry.

DEATHS IN THE SERVICES.

Surgeon William Godfrey Peck, R.N., at Malta, on July 28th. He received his appointment as Surgeon in November, 1894.

Fleet-Surgeon Charles Albert Macaulay, at Wei-Hai-Wei, China. He entered the Royal Navy in 1875, was promoted to Staff-Surgeon in 1887, and made Fleet-Surgeon in 1896. He served as Surgeon of the *Alexandra* at the bombardment of Alexandria in 1882; landed with the Naval Brigade at Alexandria, and was also at the seizure of Port Said. He was with the Naval Brigade at Ismailia, and was present at Tel-el-Kebir and subsequent advance to Zagazig (Egyptian medal, Alexandria and Tel-el-Kebir clasps, Khedive's bronze star, and the Fourth Class of the Order of the Medjidie).

Surgeon-General John Fullarton Beatson, C.I.E. (late

Bengal Army), on the 29th ult., at his residence in London, aged eighty-two years.

Inspector-General of Hospitals John Murray, at Sheringham, Norfolk.

OUR INDIAN FRONTIER.

The latest news received at Simla regarding our Indian frontier is not altogether satisfactory. It points to possible future troubles in this direction and in the Tochi valley. There has been some fighting among the tribesmen and their chiefs. The Afridis are quiet as far as the Indian Government is concerned but are quarrelling among themselves.

THE ROYAL ARMY MEDICAL CORPS FOR INDIA.

The *Pioneer Mail* of the 22nd ult. states that in consequence of the publication in this country of the new warrant reconstituting the Army Medical Service the Indian Government have been asked to submit proposals in regard to the Indian Medical Service. This is only what might have been anticipated.

THE SOUDAN CAMPAIGN.

The Anglo-Egyptian Expeditionary force will soon be starting for Khartoum. The troops are in good health and fettle and all the necessary preparations for the campaign have been made.

Correspondence.

"Audi alteram partem."

THE BATTLE OF THE CLUBS.

To the Editors of THE LANCET.

SIRS,—Mr. Cecil Aloysius Corke of Wem, Salop, has been elected surgeon to the Court Vale of Evesham, No. 4648, of the Ancient Order of Foresters in lieu of my partner and myself who resigned, as you are aware, in consequence of our salary being reduced after twenty-five years. Six other medical men, so I am informed, made inquiries, but finding how we had been treated refused to have anything to do with a society which had behaved to us in such a manner.

I am, Sirs, yours faithfully,

Evesham, July 31st, 1898. A. H. MARTIN.

*** There is no law, written or unwritten, to prevent Mr. Corke from putting his own value on his services. Perhaps Mr. Corke did not know the circumstances under which the vacancy occurred.—ED. L.

"PIPERIDINE AS A URIC ACID SOLVENT."

To the Editors of THE LANCET.

SIRS,—We say in the conclusions which terminate our article in THE LANCET of July 23rd that the dose of piperidine tartrate is 15 gr. three times a day. We think it wiser, however, to state that we have for the most part employed it in 10 gr. doses as stated earlier in our paper and should suggest this as a dose for the commencement of treatment.

We have read with interest Dr. Luff's letter on "The Treatment of Gout by Piperidine" in THE LANCET of July 30th. We are afraid, however, that the differences between us, both with regard to technique and results, are too extensive to be adequately treated in letter form. We are perfectly acquainted with Dr. Luff's paper in THE LANCET of June 11th. It was not mentioned in our paper because although the latter only appeared on July 23rd it left our hands at the end of April. This later paper of Dr. Luff will be considered fully elsewhere.

We are unable to follow Dr. Luff's calculations. In THE LANCET of June 11th he says that in order to have a 0·1 per cent. solution of any drug in the blood 600 grains must be introduced into the circulation at once. If the figures in his letter of July 30th be calculated back it will be seen that he now says that 750 grains are necessary to produce this result. For our part the one statement is as extraordinary as the other. The blood in a man of average weight weighs about 5 kilos.[1]; if 750 grains, that is, 50 grms., of any drug be introduced into the circulation at once the blood must contain 1 per cent. of it, not 0·1 per cent.; if 600 grains were introduced the amount would be 0·8 per cent.—that is, about ten times the figure given by Dr. Luff. We made experiments with standard solvent exactly similar to the ones described, adding amounts of the respective drugs down to 0·01 per cent. In each case we found that the drug exerted a solvent action directly proportional to the results given in our table on p. 202 of THE LANCET of July 23rd, as also was the case in urine for uric acid and urinary sediments (pp. 200 and 201). When worked out this amounts to the fact that piperidine in 0·01 per cent. solution increases the solvent power of standard solvent for sodium biurate one and a half times.

With regard to the question of uric acid in bullock's serum. We maintain that our experiments show that this substance is contained in bullock's serum to the extent of 0·00029 per cent.; the manipulations to which we submitted the serum constituted not only a quantitative but a qualitative test for uric acid and rendered the murexide test unnecessary. The use of the murexide test would have cost us a certain quantity of serum and has already been applied with a positive result by Abeles. We are quite aware of the work of von Jaksch, Klemperer, and Sir Alfred Garrod. The consensus of opinion seems to us to be that there is uric acid in very small quantities in the blood of man and animals under normal conditions. This is stated in the following text-books: Neumeister,[2] Hammarsten,[3] and Schäfer,[4] in addition to those mentioned in our original article.

We are, Sirs, yours faithfully,

F. W. TUNNICLIFFE.

"THE RECTAL INJECTION OF THE SERUMS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 30th, p. 279, a letter by Dr. J. E. O'Connor draws attention to the value of rectal injections in serum therapeutics, a plan evidently supposed to be original. A reference to the *Medical Digest and Appendix*, Section 886, 4, will enable those interested to obtain a large amount of information upon the subject, and in THE LANCET of Feb. 8th, 1896, p. 389, and of March 7th, 1896, p. 641, a paper published since the last issue of the *Medical Digest* enters fully into the subject.

I am, Sirs, yours faithfully,

RICHARD NEALE, M.D. Lond.

Hampstead, N.W., Aug. 3rd, 1898.

"ON FAILURE OF BRAIN POWER."

To the Editors of THE LANCET.

SIRS,—I am well aware that in general critics must not be criticised, because if this were allowed it would often go very hard with them. At the same time, an author who finds his views materially misrepresented in a review of his book is unquestionably justified in protesting against palpably erroneous statements.

Such a one I find in the review of my book "On Failure of Brain Power" in THE LANCET of Aug. 6th, where I am credited with the opinion that the affection which I am discussing is due to *definite disease* of certain special areas of the brain. "Definite disease" is equivalent with "organic disease" or "structural lesion." Now I have been at particular pains in my book to show that no organic lesions occur in the affection under consideration, but that the malady is owing to the finer nutrition of the neurones of the brain being impaired through insufficient supply of blood and intracellular oxygen (p. 215). If my critic had used the word "disorder" instead of "disease" he would have more accurately represented my meaning.

I am really quite sorry to find he does not consider my teaching on the nature and treatment of the malady "well founded"; but surely an author must sometimes be a little in advance of his time, for why should otherwise books be written? I do not entertain the slightest doubt that in five or ten years time, if not sooner, my views on this subject will be generally accepted by the profession, as I find in practice every day fresh proofs for their correctness.

I am, Sirs, yours faithfully,

JULIUS ALTHAUS, M.D. Berlin.

Queen Anne-street, Cavendish-square, W., Aug. 7th, 1898.

THE PUBLIC CONTROL OF WATER-SUPPLIES.

To the Editors of THE LANCET.

SIRS,—For some six months past we have had the subject of "Public Water Analysis" before the Tunbridge Wells Borough Improvement Association for consideration, and in March we took some action with a view to moving in the direction which your able article[1] upon the same matter touched upon. We have arranged with Maidstone, Crowborough, and other associations to form a deputation and to urge upon the Government the desirability of an Act being passed to carry out such an important proposal. Mr. Cornwallis (the Member for Maidstone) has been interviewed upon the matter and the result you may have seen. Mr. A. S. Griffith-Boscawen, M.P. for Tonbridge division, has also been assisting, and I should think if we could form a strong deputation it might have some weight in helping on the idea. I shall be glad if you could kindly again draw further attention to what is being done and state that the honorary secretary of the Tunbridge Wells Borough Improvement Association would be glad to hear from any society interested in the question, or from any individual prepared to support or willing to join as a representative to assist in augmenting the deputation being formed so as to make it as important as possible. Arrangements are in hand in order that some public and definite expression of opinion may be placed before the proper quarters.—I am, Sirs, yours faithfully,

D. G. CORNWELL, Hon. Sec.

Grove Hill-road, Tunbridge Wells.

THE NATIONAL DEPOSIT FRIENDLY SOCIETY.

To the Editors of THE LANCET.

SIRS,—The following is a copy of a letter addressed to the General Secretary of the National Deposit Friendly Society in answer to an application for observations on the medical tariff of the Society.

I am, Sirs, yours faithfully,

Cardiff, Aug. 6th, 1898. T. GARRETT HORDER.

To F. Letchfield, Esq., General Secretary, National Deposit Friendly Society.

DEAR SIR,—In accordance with your wish I have examined the pamphlets, &c., you were good enough to send me some little time since. I may remark before I enter into details that I have had considerable experience with friendly societies, and that long since I came to the conclusion that it would be a good plan to pay the medical officers of such societies for actual work done in attendance on the sick members. Of course, in arranging the fees to be paid, two things had to be taken into consideration—namely, the proper and sufficient remuneration of the medical officers and the position in life of the members of the society. I freely admit that it is not an easy matter to settle the amount of the fees to the entire satisfaction of both these parties.

According to your rules the following are the fees paid for medical cases in your society:—

	s.	*d.*
One visit with medicine for two days	2	6
Ditto beyond three miles, extra per mile	0	6
Members entitled to over 5*s.* daily sick pay, extra for every 1*s.* above 5*s.* per visit	0	6
Intermediate visits in dangerous cases, extra per visit	1	0
Attendance at surgery and medicines for two days ...	1	6
Fresh supply of medicine for two days	1	0

I notice that some alterations have been made in the above and that now an extra fee of 6*d.* is allowed for cases outside the two-miles radius, that 1*s.* extra is allowed for visits paid between the hours of 9 P.M. and 8 A.M., and that 6*d.* extra is allowed for attendance at the surgery between these hours.

I candidly confess that I do not think the terms offered are sufficiently liberal. To ask a medical man to travel four miles, and supply medicines in addition for a fee of 2*s.* 6*d.*, is hardly reasonable or fair. Neither is the allowance of 6*d.* per mile for visits paid outside the two miles radius nearly sufficient. Again, the extra allowance for night visits and night attendances is far too small. Supposing a member sent for the medical officer in the middle of the night, and the member lives nearly two miles from the doctor's house, do you think the fee of 3*s.* 6*d.* would be a fair and reasonable one for such a journey? With respect to "intermediate visits in dangerous cases" it is not quite clear to me whether the medical officer would receive 3*s.* 6*d.* or 1*s.* for such visits. If it is the latter sum, then I must say it is altogether inadequate.

As it is of the highest importance that candidates should be properly examined by the doctors before being admitted I would suggest that the fee for such an examination should be raised from 1*s.* to 2*s.* 6*d.* That a stricter examination is more necessary in your society than in the ordinary friendly societies is evident from the fact that you admit members up to fifty-five years of age.

I am, dear Sir, faithfully yours,

Cardiff, Aug. 5th. T. GARRETT HORDER.

[1] THE LANCET, April 23rd, 1898.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—I have read with great interest the correspondence in THE LANCET under the above title. Now, Sirs, I am sure that anyone who has read the correspondence cannot fail to see that there is something seriously wrong with general practice, as undoubtedly the letters represent the opinions of the majority of general practitioners. Speaking personally, although a young man I have had experience as an assistant in several practices and have a father and two brothers all in separate practices as well as having been intimately associated for many years with general practitioners. The result is that I have never yet known one who *cæteris paribus*, and presuming that he fulfils his duties properly, has not what "Practitioner"[1] describes so aptly as "a life of hardship, a scanty income, constant harass," &c., and I am so disgusted with the life of the ordinary medical man that had I the opportunity I would even now make a fresh start at another calling, although I love the work *per se* and the study of medicine. As regards the question of employer and assistant I think there is a lot to be said on both sides. My first assistantship produced £80 per annum, indeed, and was not a happy one. Although well treated as far as board and lodging and courtesy went, the life was wretched, as I was so tied down—always on duty, except perhaps for an hour in the day and after 8 P.M., when one was just as likely to be called out as not; no opportunity for games, and as my employer generally went out every night I had to be in, and if allowed a few hours to run up to town once a month to visit a theatre it was considered sufficient. But I do not think the salary was inadequate, as I am sure the expenses of a practice *at present* are so heavy, owing to poor fees, clubs, and underpaid appointments, that any practitioner doing less than £1000 a year cannot afford to pay more to an assistant than £100 a year indoor, if he wants to put by anything at all, although the average salary of a qualified assistant, which I should put as £70 per annum, is indeed what one would pay a *first-class butler*. And now let me consider why the general practitioner is so hard pushed and if a remedy can be pointed out.

In the first place, thousands of pounds which ought to go to medical men go to quacks—i.e., herbalists and bone-setters—and prescribing chemists. And, as "Assistant"[2] says, the General Medical Council ought, in the interests of the public as well as in those of the general practitioner, to immediately suppress them, and I am glad to see the Home Secretary promised recently in Parliament to give the matter his attention. Let us hope he will do so. And here I may mention that in Denmark at any rate prescribing by chemists is illegal.

Secondly, we have medical fees, and, as "M.B., B.Ch. Dubl."[3] suggests, these should be fixed by law. I daresay this would be difficult, but suppose that the General Medical Council obtained powers to maintain a proper standard of professional etiquette. I take it that to attend people at starvation fees is or ought not to be etiquette. The Council can erase a man from the Register for advertising, why not for taking halfpenny fees, as this is degrading? Supposing they enacted that any man who took midwifery under £1 1*s.* a head, and who visited under 2*s.*, and supplied medicine and prescribed under 2*s.* a head, and who engaged to attend anyone in a club under 7*s.* 6*d.* per annum—which is only 1¾*d.* per week—would be guilty of unprofessional conduct what a difference it would make. And I consider that all men earning over 15*s.* a week are able to pay 1¾*d.* per week for medical attendance. All those who could not afford to pay this should be treated by the parish or hospital and consequently the Local Government Board would have to raise their salaries. These, again, are a great grievance, as all the Poor-law medical appointments are underpaid. My father, for example, has five parishes under him with a total of about 100 paupers some five miles distant, and others two or three, and he is expected to attend and provide them with medicine for about £30 a year. This is disgraceful, and why should it be so seeing that solicitors holding Poor-law appointments are at any rate fairly paid?

I cannot think the Local Government Board can be aware how underpaid these posts are or they would try to remedy the evils. And medical officers to clubs should all

[1] THE LANCET, July 9th, 1898, p. 104. [2] THE LANCET, July 2nd, 1898, p. 53. [3] THE LANCET, July 23rd, 1898, p. 229.

Digitized by Google

unite in seeing that the clubs are not abused by people well able to be private patients. Lastly, there is the question of hospital abuse, which is assuming alarming proportions and demands immediate legislation.

To sum up, who is responsible for this state of affairs? The answer is apparent—the General Medical Council. Why do they not adopt more stringent remedies? Because that body consists almost entirely of consultants with scarcely any general practitioners and these men do not know and cannot understand what hardships the general practitioner has to contend with and remain satisfied with a few trifling reforms. I am sure that if they had an equal number of consultants and general practitioners on their staff a great deal more would be done for professional etiquette. I commend their recent action with regard to unqualified men, hard though it may be on some, for is it not a case of "the survival of the fittest"? and we are the fittest.

Our only chance is to immediately agitate to get the same number of general practitioners on the Council as there are consultants, or even more, as we are undoubtedly the body of the profession and therefore ought most certainly to have our own representatives in sufficiency, and then the Council will obtain from Parliament more extensive powers to enable them to raise the standard of, to mitigate the evils affecting, and to remunerate more properly the body of the profession.

I call therefore on all those who have written on this subject recently and all those who are interested in and approve of this scheme to join with me and at once enrol ourselves into an alliance of general practitioners, call it what you will, and to invite all other medical improvement associations to join us in one great body and let us start a journal devoted to the subject or ask permission to inaugurate our society in the columns of THE LANCET—that journal which has already done so much to raise the dignity of the profession; and, in the first place, petition the General Medical Council to allow us to be more fitly represented on their rolls and then urge upon our representatives to take immediate action to reform the state of the profession.

I am, Sirs, yours faithfully,

ASPIRATOR.

ADDRESSES AT MEDICAL CONGRESSES.

To the Editors of THE LANCET.

SIRS,—The Presidential Address of Sir Thomas Grainger Stewart at the recent meeting of the British Medical Association in Edinburgh was more than a *résumé* of medical progress during modern times, but not so much more that it would be very unfair so to describe it. Professor Fraser, in his Address in Medicine, gave a brief history of pure medicine during the twenty-three years which had elapsed since the last meeting of the Association in Edinburgh. Professor Annandale recorded the advances of modern surgery in the first part of his Address in Surgery. All three learned gentlemen gave thoughtful and informatory addresses, but I question whether their hearers would not have preferred that a more personal note should have been struck. It has lately become the invariable custom for the addresses at medical congresses—I refer in particular to those delivered in plenary assembly, but the Presidents of Sections often do exactly the same—to assume the form of stocktaking. This sort of address is disappointing to the general practitioner. Eminent physicians and surgeons are wasted in delivering such speeches, for the subject matter lies within the ken of their audience beforehand. What the medical public desires to get from its leaders is a personal expression of opinion upon something; they seek a sign, not a summary. It must not be supposed that I do not recognise the pains and the erudition which have gone to the making of the addresses which you published last week and the week before. I recognise their value, but, the speakers being the men that they are, I cannot but regret that their audience did not have from them something more distinctive.

I am, Sirs, your obedient servant,

Aug. 8th. M.B.

VENESECTION IN CHRONIC BRIGHT'S DISEASE.

[DR. SAUNDBY requests us to publish the following letter which he has addressed to Professor Ewald.]

DEAR PROFESSOR EWALD,— the Section of Pharmacology and Therapeutics at Edinburgh, during your speech on the treatment of chronic Bright's disease you expressed surprise that in the last edition of my lectures on Renal and Urinary Diseases I had omitted all reference to the value of bleeding in uræmia. I could only reply that if that were the case it was an undoubted omission, although it was rare for me now to have recourse to bleeding in these cases. On returning home, however, I have turned to the place in my book and find you were mistaken, as on page 177, under the heading "Treatment of Uræmia," are these words: "In obstinate convulsions 12 to 16 ounces of blood may be taken from the arm. Hemiplegia and coma call for bleeding to the like amount, but the hot-air bath recovered one patient from coma after the attempt to bleed had failed."

I am sending this correction to the press.

Yours faithfully,

ROBERT SAUNDBY.

Edmund-street, Birmingham, Aug. 6th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Probable Duration of the Plague Epidemic.—Lessons from History.—Hope from further Scientific Investigations.

NOW that the plague has so greatly subsided in nearly every place which has been attacked speculation is rife not only as to the recurrence of further outbreaks but as to the probable duration of the plague. That its apparent extinction in a district is no guarantee against a re-importation or a recrudescence has unfortunately been proved by many instances. The gradual spread of plague over a larger and larger area is also an additional source of danger for the perpetuation of the scourge. The clearest indication as to its further continuance seems to be derived from the history of plague in former times. It is generally recorded to have attacked districts or towns for a number of years in more or less regular succession. In Central India it existed from 1813 to 1821, in Kathiawar from 1816 to 1821, in Gharwal from 1849 to 1854, again from 1875 to 1877, and a third time from 1884 to 1897. In Hong-Kong it has lasted since 1894. Older writers describe what was probably plague as existent in the Punjaub from 1618 for eight years, in Ahmedabad from 1683 to 1689, and in Surat from 1684 to 1690. Short intervals of apparent freedom have characterised nearly all these outbreaks. In most cases it appears that the larger the population of a town or village the greater seems to be the virulence and intensity of the outbreak and the longer its duration. The older records, while obviously incomplete, seem to show that a much larger proportion of the population was carried off by the disease in former epidemics than has been recorded anywhere during the present visitation of plague. While there is some comfort from the latter observation there is very little hope of escaping from a further series of outbreaks for perhaps many years to come. On this point Dr. Roux has expressed his opinion that plague in India "would remain with us in Bombay for a long time." He affirmed his belief that it would be several years before we should see the last of it. Dr. Yersin has also stated that plague would be a recurring epidemic for many years. It must be admitted that all our sanitary measures have failed to eradicate the disease. While we stick to all sorts of repressive sanitary measures which were exceedingly difficult and almost impossible to apply, and have proved over and over again almost complete failures, we have amongst us several foreign *savants* who are working on quite different lines — for prophylactic inoculation, M. Haffkine; for curative serum, Dr. Simond, as representing Professor Roux and the Pasteur Institute; and Dr. Gallioti, representing Professor Lustig of Florence. As there is no difficulty in the manufacture of either the prophylactic fluid or the various kinds of curative serum, and as both offer some hope of success, it seems extraordinary that the Government does not engage English men of science to pursue further investigations in these directions. Both systems are capable of very considerable improvement. It is impossible that the expensive methods of sanitary control as hitherto adopted can go on for years. Every city would be bankrupt and perhaps India in insurrection, so that either plague will have to be left almost entirely to take its own course or experimental science must step in and supply

Digitized by Google

the antidote. Prophylactic inoculation is attended by the practical difficulty that we can only get a small proportion of the people to be inoculated. Like vaccination for small-pox it can only prove really successful when performed on a large scale. On the other hand, a curative serum if successful would rob the disease of its terrors and make the early discovery of fresh cases possible. Hope from this quarter is engendered by the better results from the most recent experiments. If it were possible to reduce the mortality to 20 or even to 30 per cent. plague would be almost disregarded. By these scientific means and by these means alone conquest over the plague seems possible.

July 16th.

THE SPANISH-AMERICAN WAR.

(FROM A SPECIAL CORRESPONDENT.)

Camp Cuba Libre, Jacksonville, Fla., July 26th, 1898.

MEDICAL officers as well as line officers are all anxious to go to the front. My experience is limited to one army division, but in this one division hospital, the medical wards of which are under my charge, many interesting problems are continuously presenting themselves. The hospital of the Second Division of the Seventh Army Corps is in a pine-grove near the division camp. It consists entirely of tents. A central circular thirty-foot tent forms a convalescent ward, and radiating from this the floored army hospital tents are arranged in rows of six, the six being broken into groups of twos by arbors which admit air and permit of separation of the patients. There are additional single isolated tents for the treatment of the acute or noisy cases, and for a surgical operating-room, clinical office, and dispensary. The medical officers' tents face the hospital at a distance in its front, and the hospital corps nurses and stewards are encamped in the rear. Each hospital tent contains six large and comfortable canvas-covered cots. Over each cot, pinned into the seam of the canvas, is a curtain-hook pin on which hangs a printed clinical chart bound in pad form. These forms I devised and they were printed for me by the Red Cross Society.

The sickness in this command, though not excessive, is already so great as to have increased this hospital beyond its regulation size. We have now about 250 patients, in great part medical—indeed nearly all are fever cases. The fevers are typhoid and malarial, nearly all of the fatal cases being typhoid fever. There were from May 29th to July 22nd 808 patients admitted to the hospital, with 13 deaths, in a command of 13,000 men.

The one great favourable feature of this camp is its most excellent water-supply. Artesian water in unlimited quantities is piped to the entire camp. This water is above the suspicion of germ contamination and its properties are of the best. The source of supply is constantly guarded, to prevent poison being added to the water, though the poison which could be used to contaminate such great quantities of water I have found no one able to suggest.

This, in brief, is the situation with this army division. We have good water, hot sun, heavy rains and dews, the intemperance usual in armies, and some necessary work. The result is much typhoid fever and more of the shorter continued malarial fevers, of which I may write you more.

We have had in all three interesting epidemics of typhoid fever. First, nearly all our cases came from the Virginia regiments. The men reported bad water at the Richmond camp. Post-mortem examinations showed the most pronounced lesions. The second epidemic occurred in Company F of the Second Illinois Regiment. On May 30th the members of this company were severely poisoned by the meat served them. Nearly all the men suffered with severe abdominal pains, vomiting, and diarrhœa, some even becoming unconscious. Two weeks later we had very many men sent to the hospital from this company with typhoid fever. Three of these patients died, two with perforation, one with meningeal symptoms. Did the beef contain the typhoid bacilli? Last week our third epidemic began. From the First Wisconsin Regiment we have had 60 admissions, many of which are developing typhoid fever. One unexpected fact is presented by a study of our records. In June, the six Northern regiments in this division sent 172 men to the hospital, while the three Southern regiments sent 216 sick men to us—the South thus, with half the number of regiments, sending 25 per cent. more patients. One would have thought that Southern men could stand the Florida climate better than Northerners.

I believe the hospital corps is the hardest worked part of the army, even without any other battle than that with disease germs. We volunteers find the regular army surgeons most pleasant. They overlook our lack of knowledge of military forms and facilitate our work in other respects. All realise the difficulty of hastily meeting the needs of so great a military force at once and attach little importance to hastily made and unjust criticisms of the medical department of the army.

But no one should write from the front without giving great credit to the Red Cross Society for the great work it is doing. Without the aid of this society it would have been difficult to care for the sick in this hospital. Each day the Red Cross gives us 50 gallons of milk, 2000 pounds of ice, 30 dozens of eggs. Besides this it has built for us storehouses, floored our tents, given us hundreds of night shirts, pyjamas, pillows, sheets, buckets, bedpans, and dozens of other articles necessary for the care of the sick. In military channels the stream of supplies flows slowly and with many stops and much formality, but Dr. Kent, who represents the Red Cross here, gives freely and without delay. He has no regulation that prescribes how many bed pans one division must use, but gives all which are needed. This week, with the people of Jacksonville furnishing the motor power, he is going to put electric fans in all the tents.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Prosecution under the Factory Act at St. Helens.

A PROSECUTION was instituted at St. Helens Police Court under the Factory Act, 1891, against Richard H. Twist for a breach of the Act in not providing the workpeople in his factory with suitable overalls and headpieces as a protection against lead-poisoning in the manufacture of china and earthenware, such as pans, mugs, &c., which have to be glazed by means of the use of lead. Mr. Grant, the Government inspector under the Factory Acts, visited the works on July 1st and found a man and a woman engaged in the process of preparing the china for dipping. He found that they had no overalls and never had had any. The man had worked there for some years and owing to a serious illness which was pronounced by Dr. Casey to have been due to lead-poisoning was laid up for six months. The defendant controverted the statement that his employé was suffering from lead-poisoning and said that his illness was due to the effects of drink. He stated that he used very little red-lead, but mainly lead-ore, and that he did all the mixing himself; that the girls and men had merely to wash the pails round. He also stated that there were no dust and no brushing. The inspector pointed out to the magistrates that the danger to individuals engaged in these works arose from actual contact with the lead. They got the lead over their hands, and it got under their finger-nails and through the pores of the skin. As the defendant had fairly observed the rest of the rules as regards the manufacture of his special wares the magistrates decided not to convict in this case, but cautioned the defendant against a similar breach of the regulations of the Factory Act in the future.

Revocation of the Appointment of a Medical Referee under the Workmen's Compensation Act.

The appointment of Mr. J. D. Crawford as one of the medical referees under the Workmen's Compensation Act to Circuit No. 6, which was notified in THE LANCET of July 16th, has been cancelled by the Home Secretary. Dr. Thomas Clarke, the chairman of the hospitals committee of the Liverpool City Council, has been appointed in Mr. Crawford's place.

Liverpool Consumption Hospital.

Lady Willox, the wife of Sir John Willox, the member for the Everton Division of Liverpool in Parliament, has been the means of raising the sum of £200 towards the new building fund through a bazaar promoted by her ladyship at the hospital.

Liverpool Assizes: False Charge against a Wigan Surgeon.

The grand jury threw out the bill in the case of Mr. James

Digitized by Google

Brown, who had been indicted on the inquisition of the coroner for the wilful murder of a Mrs. Sharples by performing an illegal operation upon her at Ince. The charge rested upon such slender foundations that the case had been dismissed at the usual magisterial inquiry previously held. The grand jury had no hesitation in ignoring the bill, believing the charge to have been groundless. Mr. Brown is to be congratulated upon the result and at the same time deserves much sympathy for having been placed in such a terrible position.

Low Death-rate at Southport.

The death-rate at Southport during the month of July was exceptionally low. Locally it was only 7·82 per 1000 of the inhabitants. The gross death-rate was 9·48 per 1000. These figures compare favourably with those of the corresponding period of last year which were 10·21 and 12·88 per 1000 respectively.

August 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Congress of the Royal Institute of Public Health in Dublin.

THE Lord Mayor and corporation of Dublin have agreed to the request of the Exhibition Committee of the Congress to be present in state on the occasion of the opening of the Health Exhibition at Earlsfort-terrace on Aug. 18th and the High Sheriff has sent out numerous invitations to a luncheon at the Royal University Buildings for the same day. The hon. secretary of the Congress Hospitalities Committee has reported that in consequence of the large number of applications which have been received for tickets for the banquet at which His Excellency the Lord-Lieutenant will be present on Aug. 20th, the committee have been compelled to direct the attention of the public to the fact that the accommodation at the Royal College of Surgeons in Ireland is of a limited character. The following is a list of those who previously to Aug. 5th had signified their intention of attending the banquet:—General Dunham Massy, C.B., the Right Hon. the Lord Chancellor of Ireland, Professor Armstrong (Edinburgh University), the Right Hon. the Lord Mayor of Belfast, the Right Hon. Viscount Bangor, Mr. A. C. Cope (Board of Agriculture), Baron De Robeck, Sir George Duffey, the Right Hon. Baron Emly, Mr. John Kells Ingram, LL.D., Mr. Thomas Stafford (Local Government Board), Mr. Henry Jones (hon. secretary to the Royal Institute of Public Health), the Hon. Mr. Justice Kenny, the Right Hon. the Lord Mayor of Liverpool, the Right Hon. Viscount Monck, the Right Rev. Gerald Molloy, D.D., D.Sc., Dr. James Creed Meredith, LL.D. (secretary to the Royal University, Ireland), the Right Hon. Viscount Powerscourt, Dr. Salmon (Provost of Trinity College), Sir Andrew Reid, K.C.B., LL.D., Hon. Mervyn R. Wingfield, Mr. T. W. Russell, M.P., Professor W. R. Smith, M.D., D.Sc., the Mayor of Huddersfield, Mr. J. J. M'Grath, LL.D. (secretary to the Royal University), Baron de Brault, the High Sheriff of Dublin, Professor Shaw (Trinity College, Dublin), Mr. J. C. Thresh, M.D. Vict. (Chelmsford), Lord Rosse, and Mr. Thomas A. Mooney, LL.D. (secretary to the Local Government Board). At a meeting of the Hospitalities and Excursions Committee, held on Aug. 5th, Sir Christopher Nixon stated that a number of the members would be invited to inspect the Mater Misericordiæ Hospital, where light refreshments would be provided. Many other entertainments, &c., have been announced for the guests, including those which are noted in the following abridged list: Thursday, Aug. 18th.—A luncheon by the High Sheriff of Dublin at the Royal University Buildings. In the afternoon Surgeon-General and Mrs. Preston will give a garden party at Moncktown, while in the evening a dramatic and musical entertainment will be arranged by the Corinthian Club at the Lyric Hall, and a promenade concert at the Health Exhibition. Friday, Aug. 19th.—Organ and pianoforte recitals at the Royal University and luncheon at the Mater Misericordiæ Hospital, and a garden party at Clonskeagh, where Sir Christopher and Lady Nixon will entertain the guests. In the evening the Lord Mayor will welcome all the visitors at a ball in the Mansion House. Saturday, Aug. 20.—Alderman the Right Hon. J. M. Meade and Mrs. Meade will give a garden party at Merrion, and there will be a banquet at the Royal College of Surgeons in Ireland, at which the Lord-Lieutenant will be present. On Monday the Lord Mayor of Belfast will receive visitors there at a luncheon, while excursionists to the county Wicklow will be entertained by Sir Henry and Lady Cochrane at a garden party at Bray.

The Apothecaries' Hall of Ireland.

The first examination by the Apothecaries' Hall of Ireland, in conjunction with the Royal College of Surgeons in Ireland, which has been held since the decision of the General Medical Council and the appointment of the new board of examiners has just concluded. Two candidates are announced to have passed the final examination.

The Surgeoncy to the Dublin Metropolitan Police.

Dr. Henry Oulton has just been appointed chief surgeon to the Dublin Metropolitan Police.

Sanitary Condition of Magherafelt.

The Local Government Board have written to the Magherafelt Board of Guardians drawing their attention to a report of Mr. Vesey, medical officer of health, relative to the insanitary state of that town and giving their opinion that a large portion of the place was much in need of improved sewerage and that the guardians would incur grave responsibility should an outbreak of infectious disease occur in consequence of their failure to remedy the defects pointed out by Mr. Vesey. The matter has been referred to the Magherafelt Dispensary Committee for further consideration.

Queen's College, Belfast.

Her Majesty's Commissioners for the 1851 Exhibition have intimated to the President of Queen's College that they have nominated that institution to a science research scholarship of the annual value of £150 tenable for two years. The person nominated must be an alumnus of Queen's College, Belfast.

The Belfast District Lunatic Asylum.

At a meeting of governors held on Aug. 8th it was decided, in reply to a letter from the Board of Control, that notwithstanding the urgency for the building of the new asylum at Purdysburn it would be wise to fall in with the suggestion of the Board of Control and postpone the matter for a few months until the Local Government Bill becomes law. The committee appointed to examine into the sewerage system at Purdysburn reported that they endorsed the statement of their medical superintendent that it was inadequate and uncertain in its action. I am afraid that eventually the sewers of the asylum will have to be connected with the main town drainage system. The committee of governors report most favourably of the way in which Dr. Graham (the medical superintendent) has carried out his plan of a dairy and tillage farm at the asylum. They found every department in a most satisfactory condition, but they regret that the most valuable portion of the tillage ground will be taken from them for the site for the new Infectious Diseases Hospital, as it is in this part the test crops have been grown and it is better adapted for cultivation than any other portion of the farm.

The British Pharmaceutical Conference at Belfast.

The thirty-fifth annual conference of this association opened in Belfast on August 9th, the meeting being held in Queen's College, when the members were welcomed on behalf of the city by the Lord Mayor (Alderman Henderson, M.A., J.P.) and by the President of the College (Dr. Hamilton). The chairman and members of the Ulster committee gave a reception and conversazione in Queen's College on the same evening, and the Lord Mayor is to entertain the members and his friends at a garden party on Aug. 10th. Thursday is to be devoted to a coast trip in county Antrim. The President of the society this year is Mr. Charles Symes, Ph.D., F.L.S., of Liverpool. Nineteen papers are announced on the business programme.

August 9th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Results of Suprapubic Cystotomy in Cases of Enlarged Prostate.

AT the meeting of the Academy of Medicine, held on August 2nd, M. Poncet of Lyons read a paper treating of the results obtained by creating an artificial opening into the

Digitized by Google

bladder, of either a temporary or a permanent nature, the opening being above the pubes, in cases of prostatic trouble. Since 1895, M. Poncet has performed or caused to be performed 81 suprapubic cystotomies, and the total number of cases to which he referred was 114. Of these 114 patients 87 recovered and 27 died. M. Poncet divided the 114 cases into three groups. Group 1 comprised 39 patients who presented no symptoms of uræmic or other toxic affection and of these 37 were cured. Group 2 comprised 29 patients suffering from acute uræmia at the time of operation, and of these 12 died. Group 3 comprised 46 cases of chronic uræmia, and of these operations 33 were successful and 13 patients died. These figures show that success in the operation of suprapubic cystotomy is in direct relation to the gravity of the patient's condition as regards the general condition and the degree of uræmic poisoning, from which M. Poncet argued that early intervention was essential. The operation entirely does away with urinary retention and all its accompanying effects which are so generally fatal. In support of his arguments M. Poncet brought forward many cases, among which were the two following: A patient aged seventy-eight years, who was suffering from uræmic coma, and had a rectal temperature of 40·6° C., was operated upon. At present, four years and a half after the operation, he is well, and can hold his urine for three or four hours during the day and for even longer at night. All the urine passes by the hypogastric opening. Another patient operated upon six years ago to-day follows his occupation of a blacksmith. He can retain his urine for from three to five hours. It is passed by the hypogastric opening, and the jet is projected for a distance of thirty or forty centimetres.

The Nantes Congress.

On Aug. 5th the annual meeting of the French Association for the Advancement of Science commenced at Nantes. The medical section revealed some features of great interest and the meetings passed off by no means quietly. Sundry disturbances occurred in the town owing to the choice as president of the meeting of Professor Grimaux, who is extremely unpopular among the townspeople on account of the part which he took in the recent Zola trial. The inhabitants of Nantes have held several demonstrations in the streets demanding his withdrawal from the presidentship. Three or four times has the venue of the meetings been changed on account of its being impossible for the president to obtain a hearing. Finally they had to be held in a room at the College only capable of holding very few listeners and from which the public were rigorously excluded. The most interesting discussion was that upon Diabetes, introduced by Professor Lepine of Lyons. By means of a statistical statement drawn up with great care from the civil registers and the hospital reports of the city of Lyons M. Lepine was enabled to give with very fair accuracy the proportion of diabetics in the large urban districts, and the figures seem to show that this disease is actually increasing, this being in accordance with the researches of M. Bertillon. The number works out in the proportion of about 5 per 1000. M. Lepine in examining into the distribution of diabetes was struck by the frequency with which it occurred in the same communes, so that he was compelled to allow that the cause must be an hereditary one, or contagion, or due to some local influence. Dr. Loin of Tunis thought that a hot climate had something to do with it. He found diabetes to be very common in the colony of Tunis, especially among the Jews. As to its etiology, he was inclined to give the first place to errors in diet—namely, a diet very rich in starch and therefore in sugar. Want of exercise and sedentary occupations also appear to be a cause, for diabetes is very rare among working men and soldiers. There would seem to be no relation between diabetes and venereal excess or between diabetes and malaria, and the influence of alcohol is very doubtful. Climate is not sufficient to explain it altogether for diabetes is rare in the hotter countries. The commonest cause of death is gangrene but sometimes it is due to a diffuse carbuncular inflammation. Death from tuberculosis is very rare in Tunis, even among the military. Treatment by drugs is of little use but strict attention to hygienic details is everything. According to M. Leduc the principal cause lies in errors of diet and more especially of drink. The white wine so commonly drunk is very prone to produce fatty degeneration of the liver, and this is probably the principal cause. The question as to whether diabetics should be allowed potatoes brought out a variety of opinions. M. Mosse of Toulouse by dint of making many and careful analyses has arrived at the conclusion that the sugar shows a marked diminution when potatoes are substituted for bread. M. Rappin considered that the contradictory results arrived at with regard to potatoes were due to the observers not having sufficiently taken into consideration the various kinds of potatoes, variations which are shown to exist by the different ways in which cultures of bacilli develop upon different kinds of potatoes chosen as a culture ground.

August 9th.

Obituary.

WILLIAM SAVAGE SPEER, M.D., M.CH. R.U.I.

THE death is announced of Dr. Speer, which took place at his residence, Clifton-street, Belfast, from meningitis, on Aug. 3rd, after a short illness of a fortnight, during ten days of which he was confined to his bed. Born in the neighbourhood of Castledawson, co. Derry, fifty years ago, Dr. Speer received his medical education at Queen's College, Belfast, and graduated M.D. in the old Queen's University, 1874. For the past twenty-four years he had practised in Belfast, and during the early part of his career he assisted his brother-in-law, Dr. David Johnston, who died a month ago. Dr. Speer was an extremely busy man and he had one of the largest middle-class practices in Belfast. Possessed of good abilities and being most conscientious and anxious to do his utmost for his patients, Dr. Speer was greatly respected and liked by his very large *clientèle*. Apart from his position as a skilful practitioner of the healing art Dr. Speer was a deeply-religious man and he took the warmest interest in all matters concerning the church to which he belonged and for a great many years he conducted a religious service for men in connexion with one of the Belfast church associations every Sunday morning. Dr. Speer leaves a widow but no family. He was buried on August 5th at the City Cemetery, the immense concourse of patients and medical men present indicating the marked respect in which he was held. By the death of Dr. Speer Belfast and the medical profession have lost a man of great ability and of the highest honour, who spared neither time nor pains in the interest of his friends and his patients.

WILLIAM HENRY ACKLAND, M.D. ST. AND., M.R.C.S. ENG., L.S.A., J.P.

DR. W. H. ACKLAND died at Plymouth on Aug. 7th, at the age of seventy-three years. The deceased received his medical education at University College, London, obtaining the M.R.C.S. Eng. qualification in 1847 and the L.S.A. a year later. In 1862 he was admitted M.D. at St. Andrews University. Dr. Ackland was for many years a well-known and highly-esteemed practitioner at Bideford. He was formerly physician and senior medical officer to the Bideford Infirmary and medical officer of health of the Bideford Urban District, and at the time of his death was senior magistrate for the borough. Dr. Ackland took the greatest interest in the development of Bideford and the district and was an intimate friend of the late Canon Charles Kingsley. A few years after the appearance of Kingsley's "Westward Ho!" Dr. Ackland was one of the directors of the Westward Ho! Hotel and Villa Company, and he it was who suggested the name for the place after his friend's book, for Westward Ho! in those days consisted of a farmhouse and a cottage. He was for several years President of the Devon and Exeter Medical Benevolent Society. He retired from practice a few years ago and removed to Plymouth.

FLEET-SURGEON CHARLES ALBERT MACAULAY, M.D., M.CH. R.U.I.

NEWS was received in Plymouth on July 27th of the death at Wei-Hai-Wei, China, of Fleet-Surgeon Charles A. Macaulay of the flagship *Centurion*. He was taken ill on June 14th and he died on the following day. The funeral took place on June 16th, the deceased being the first to be buried at Wei-Hai-Wei. Fleet-Surgeon Macaulay joined the Royal Navy on Sept. 30th, 1875, and reached the rank of fleet-surgeon on

Digitized by Google

March 5th, 1896. He was surgeon on the battleship *Alexandra* at the bombardment of Alexandria on July 11th, 1882, and landed there with the naval brigade. The deceased was also at the seizure of Port Said and was senior medical officer of the seamen and Royal Marines who landed there. He was also with the naval brigade at Ismailia and was present at Tel-el-Kebir, receiving for his services the Egyptian medal, the Alexandria and Tel-el-Kebir clasps, the Medjidie of the fourth class, and the Khedive's bronze star.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—In Leopold von Dittel, Austria, and indeed all Europe, loses a great surgeon. He was born in 1815 and took his degree in Vienna in 1840. At first he was in general practice and it was not until he was approaching his fortieth year that he took up surgery as his special subject, becoming assistant to Professor von Dumreicher. In 1856 he was himself appointed one of the surgeons of the Vienna General Hospital and some nine years later extraordinary professor. His most important papers had reference to the surgery of the urinary organs, but his name is perhaps most generally known in this country in connexion with the method of excising tumours by means of an elastic ligature. He was very popular amongst his medical brethren and was President of the Vienna Medical Society.—Dr. Francesco Trombetta, Professor of Clinical Surgery in the Messina Medical School.—Dr. Du Mesnil, physician to the Vincennes National Asylum.—Dr. Louis E. Livingood, Assistant Professor of Pathology in the Johns Hopkins University, Baltimore.

DIPHTHERIA IN LONDON.—In the four weeks ended on July 16th the amount of diphtheria in London differed but little in the aggregate from that recorded in the preceding period of like duration ended on June 18th. In the June period the total of notifications of the disease in London, corrected for duplicates, was 828, yielding a weekly average of 207 cases, while in the July period the total was 849, giving a weekly average of 212 cases. In June two districts of London escaped invasion by diphtheria, but in the July period every sanitary area yielded cases, although in three instances only single cases were recorded, nine cases being notified in all in six districts. In June only one district had upwards of 50 cases, but in July there were five such districts, with an aggregate of 290 notifications. In the matter of mortality the 106 registered deaths of the June period, being 26 weekly on the average, gave place to 116, or 29 as a weekly average in July; and the case mortality of 12·8 per cent. of June became 13·7 per cent. in July. Thus alike for amount and fatality the two periods were not dissimilar. In the Outer Circle the 45 deaths from diphtheria in June were replaced by 41 in the July period, the weekly numbers of 11, 11, 10, and 9 making the latter total, showing an evenness of death record throughout the period.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on July 22nd, Dr. Dundas Grant, the President, being in the chair.—Dr. Furniss Potter showed a case of Subacute Myringitis affecting both membranes in a man, aged thirty-seven years, who stated that he could hear perfectly well up to the onset of his present trouble three months ago.—The President narrated a case of Thrombo-Phlebitis of the Sigmoid Sinus following Chronic Suppuration of the Middle Ear, in which recovery followed evacuation without ligature of the jugular vein.—Mr. George Stoker showed cases of Lupus and Rodent Ulcer treated with inoculations of staphylococcus pyogenes aureus previously exposed to the action of oxygen, by which Mr. Stoker thought an antitoxin was produced.—The President showed a case of Rhinoscleroma in a native of Russia, and Mr. St. George Reid showed a Culture Tube and Microscopic Specimen of the Capsuled Bacillus of Rhinoscleroma from the President's case.—Dr. Middlemass Hunt described a case in which he had performed Thyrotomy for Malignant Disease of the Larynx in a man over eighty years of age. He also described a case illustrating the effects on growth and development of removing nasal obstruction; the patient, a girl, aged seventeen years, had in seven months after the removal of nasal polypi grown 3½ in. and had gained 3 st. in weight.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT EDINBURGH.

THE SECTIONS.

SURGERY.

FRIDAY, JULY 29TH.

DR. ROVSING (Copenhagen) read a paper on Some Obscure Hæmorrhages from the Kidney and their Treatment by Nephrotomy. He pointed out that cases of hæmaturia occurred in which the blood was derived from only one kidney, as shown by the cystoscope, in which no definite cause could be assigned for the hæmorrhage. He narrated several cases of this kind in which nephrotomy had been followed by recovery. In two of the cases bacterium coli was present in the urine, but Dr. Rovsing was inclined to think that this had nothing to do with the hæmorrhage. He considers it possible in some cases that the bleeding is caused by displacement of the kidney giving rise to some venous congestion.

Dr. T. H. MORTON (Sheffield) described the chief conditions preventing replacement in dislocation of the shoulder and exhibited a Working Model of an apparatus he had designed to assist in replacing the head of the humerus. It consisted essentially of a hinged pad by which pressure was brought to bear on the bone close to the head.

Mr. R. H. PARRY (Glasgow) described three cases of spasmodic torticollis in which the deformity was persistent and long lasting and was entirely due to spasm of the muscles and not to their permanent contraction. He effected a cure in all the cases by resecting a portion of the spinal accessory nerve on one side and dividing the cervical plexus on the other, in this way removing the spasm of one sterno-mastoid and the opposite occipital muscles. The recovery was complete in all the cases (one of which was shown) and no permanent paralysis was left.

Mr. NOBLE SMITH (London) said he had treated 16 cases by this method and he looked upon the operation as well established. He had found movement return early.

Professor KOCHER (Berne) said he had frequently seen recurrence of the deformity in these cases and now he always divides the sterno-mastoid on one side and the occipital muscles on the other.

Mr. J. HUTCHINSON, jun. (London), read a paper on Removal of the Gasserian Ganglion for Trigeminal Neuralgia, illustrated by the notes of a successful case. He pointed out that there were two routes by which the ganglion might be approached: (*a*) one by resecting (temporarily) the zygomatic arch and trephining around the foramen ovale (this might be called the "pterygoid" route); and (*b*) by opening the skull through the squamous plate and raising the temporal lobe from the middle fossa without piercing the dura mater. He showed that it was not necessary to ligature the middle meningeal artery. He expressed the opinion that the temporal route would be always preferred in future, as, though difficult, the operation was accompanied by less risk than the other and much less deformity resulted.

Mr. MAYO ROBSON (Leeds) had had three cases which were not perfect successes. By the pterygoid route he thought some beneficial effect could be made on the ganglion by pulling forcibly on the third division of the fifth nerve.

Dr. W. BRUCE (Dingwall) read a paper on the Nature and Treatment of Sciatica. He attributed sciatica always to disease of the hip-joint, occurring especially in those possessing the uric acid diathesis, and he had met with success in treatment of sciatica by acting on this theory of its causation.

Dr. J. CRAWFORD RENTON (Glasgow) contributed a paper on the Surgical Treatment of Sciatica. He had found in many persistent cases that extensive adhesions existed around the nerve and recovery had followed their division. He urged the advisability of cutting down on and freeing the nerves in all cases which did not recover rapidly.

Dr. ROBERT KENNEDY (Glasgow) gave the details of Four Cases of Traumatic Musculo-spiral Paralysis in which the palsy followed fracture of the humerus. In all the cases rapid improvement followed the operation of freeing the nerve. The delayed return of muscular power in some of

Digitized by Google

these cases he was inclined to attribute to the muscles rather than to the nerves.

Mr. MAYO ROBSON (Leeds) thought that however long the time since the injury every case of traumatic paralysis should be operated on. He had seen sensation return in twenty-four hours.

Professor DOYEN (Paris) exhibited some Instruments which he had invented for Operations on the Skull. Most of them were of great ingenuity and were worked by electricity. With the use of these instruments it was possible to remove a flap of bone four inches in diameter in eight minutes. He further described a method he had devised for Resection of the Bowel. The end of each portion of intestine is closed by a "purse" suture and then lateral anastomosis is performed. Professor Doyen also gave an account of his Operation for Congenital Dislocation of the Hip. The head of the femur was freed from its attachments, a new acetabulum was made by an ingenious circular chisel, and the head was replaced. A plaster splint was then applied by special apparatus. He mentioned that the operation had proved very successful.

Mr. E. MUIRHEAD LITTLE (London) read an interesting paper on Coxa Vara. He had found twenty-nine specimens in museums and mentioned that there were two varieties, one in children caused by rickets, and the other in youths, and caused probably by carrying heavy weights. He insisted on the very great value of Roentgen rays in diagnosing this condition, and showed by some skiagraphs how frequently other deformities are mistaken for coxa vara. He considered that the best treatment was subtrochanteric osteotomy.

Mr. NOBLE SMITH (London) described a case of excessive coxa vara for which he had done osteotomy with success.

OBSTETRICS AND DISEASES OF WOMEN.

FRIDAY, JULY 29TH.

The third day's session began with the reading of a paper by Dr. R. C. BUIST (Dundee) on

Two Symphysiotomies in Domestic Practice.

The two cases were offered as evidence of the suitability of symphysiotomy for domestic practice. The first case was that of a woman aged twenty-five years. Her first and second children died in labour, the second after difficult forceps extraction; the third died sixteen hours after induced premature labour. Pelvic measurements were as follows: 21·3, 25·2, and 32 cm.; diagonal conjugate 9 cm. At seven and a half months the pelvis was enlarged by Frank's method of chiselling an anterior lamella from the pubic bones. The absolute rest induced torpidity of the bowels and tympanites, and labour came on after a week. The eight months' child was easily delivered with forceps in the right occipito-posterior position. The pegs fixing the pubic bones dragged during labour and the wound broke down. Apart from a phlebitis progress was satisfactory; the patient was walking about in six weeks and was now well. The pelvis was firmly healed and had gained 2 cm. in its transverse measurement. The second case was that of a woman aged twenty years; a primipara, rachitic; pelvic measurements being 21·5, 23, and 29 cm.; diagonal conjugate 10 cm. After two days' labour and five hours after rupture of the membranes the child's heart sounds becoming weak and irregular, and there being no descent of the head, symphysiotomy was performed by Ayers' subcutaneous method, operation and delivery occupying less than an hour. The child was nursed from the first, and in less than three months the mother was at work. The child in the first case died from bronchitis at two weeks; the second was at present well and the head was nearly normal. As premature children in this social station were practically never reared the result must be deemed satisfactory.

Professor MORISANI (Naples) said that he had not invented symphysiotomy, but had remained faithful to it since 1863, when he read a short note on the subject at the London Congress. The point to remember about symphysiotomy was that it had no scope at all with a conjugata vera of less than 70 mm., for the utmost increase obtainable by symphysiotomy in this diameter was from 18 to 20 mm., which with 70 made about 90 mm.—i.e., about the diameter of the fœtal head. He proceeded to describe the method of operation which he adopted. Some used the open incision; he preferred a quite small incision from 2 to 3 cm., opening up the articulation sub-cutaneously. The risk of hæmorrhage was sometimes made much of, but it was quite exceptional. The operation was very free from after-pain; and if antiseptic precautions were good the results were excellent for the mother. As to the child, it might die during extraction; and here the question arose whether forceps should be used or the case left to nature. This treatment had an advantage over induction of premature labour, which often resulted in weakly children.

Dr. JOHN MOIR (Edinburgh) called attention to the satisfactory results which he had obtained from the induction of premature labour in cases of contracted pelvis; he thought this procedure was preferable to symphysiotomy.

Dr. AMAND ROUTH (London) read a paper on

The Treatment of Cystocele.

He divided cystocele into primary and secondary—primary, due to injury during childbirth, and secondary, due to prolapsus uteri, &c. Primary cystocele usually leads to supra-vaginal elongation of the cervix. The treatment depended upon whether the cystocele was primary or secondary. In all cases where retroflexion or prolapsus coexisted anterior vaginal fixation of the uterus was required. For the cure of the cystocele itself he considered that whatever the form of incision adopted in the performance of the anterior colporrhaphy, the essential part of the operation was the complete stripping off of the bladder from the front of the uterus and from the anterior vaginal wall. The bladder could then be turned up out of the way and the supra-vaginal part of the uterus fixed, if need be, to the anterior vaginal wall. In cases of primary cystocele with resulting supra-vaginal elongation of the cervix amputation of that structure was also required. Dr. Routh claimed no novelty for the steps of the operation which was practically involved in anterior vaginal fixation of the uterus, but in his paper he advocated its particular applicability to the cure of severe cases of cystocele.

Professor SÄNGER (Leipsic) said that for about eight years he had been doing an operation similar to that of Dr. Routh but more extensive. Having fixed the uterus and urethra with volsella, to expose the field of operation he made a median incision and reflected two vaginal flaps; into the exposed vesical wall one or more rows of buried silk sutures were inserted, after which the flaps were resected and the edges brought together with silk. It was almost always necessary to do a posterior colpo-perineorrhaphy at the same time because the perineum was always deficient in these cases. The mistake generally made, both with the anterior and with the posterior operation, was that they were not carried high enough.

Professor FEHLING (Halle) did not think that excision of a portion of the cervix was sufficient in these cases; it was necessary to do in addition a ventro-fixation or vesico-fixation of the uterus, otherwise there was a tendency to recurrence.

Dr. ARTHUR GILES (London) divided cases of cystocele into two classes, those in which the uterus was in normal position but the vaginal wall elongated and prolapsed, and those in which the cystocele was only a part of a general hernia of the pelvic floor. In the first kind, removal of a portion of the anterior vaginal wall might suffice; in the second kind, which was due to a separation of the vaginal wall from its pubic attachments during labour, removal of part of the vaginal wall would only have the effect of fixing the uterus in a low faulty position. The real desideratum was an operation which would restore the vagino-pubic connexions. Failing this, ventro-fixation combined with colporrhaphy answered best.

Professor MARTIN (Berlin), basing his remarks on an experience of over 1000 operations, advised repairing the defects of the uterus as well as of the vagina for the restoration of displaced pelvic organs. He first did an excision of the cervix, if necessary, then curetting; then anterior colpotomy was performed, which gave the opportunity of fixing the uterus up to 2 cm. over the internal os; this was quite safe in eventual pregnancy. Next an anterior colporrhaphy was performed, and at all events a posterior colporrhaphy must be added at the same sitting. The particular method employed seemed unimportant seeing that so many good results were obtained from different procedures.

Dr. LAPTHORNE SMITH (Montreal) emphasized the view expressed by Professor Sänger and Professor Martin that it was quite useless to do an operation for cystocele alone. His practice was as follows: (1) dilatation; (2) curetting of the uterus; (3) amputation of the cervix if necessary; (4) anterior colporrhaphy; (5) posterior colporrhaphy; (6) removal of diseased ovaries and tubes when

Digitized by Google

required; and (7) ventro-fixation of the uterus. All this could be done at one sitting; and if neither the operator nor anyone else talked could be finished in an hour and ten minutes. From this practice he had got very good results.

Dr. AMAND ROUTH, in reply, said that his main contention was that it was useless to attempt to cure cystocele unless the bladder was first completely stripped off from both the uterus and vagina and turned up out of the way. At the same time vagino-fixation could be effected if the uterus was displaced. It might be necessary to also amputate the cervix if supra-vaginal elongation had secondarily occurred. In primary uncomplicated cystocele he had found the operation he had described successful after two years.

Dr. W. J. SMYLY (Dublin) read a paper on

Extirpation of the Myomatous Uterus per Vaginam.

He said that the mere presence of a myoma was not an indication for operation, but in cases of small uteri which did require operation vaginal hysterectomy with morcellation was the best method in most cases. Out of the 17 cases in which he had extirpated the uterus in this way he had lost one in which the myoma had sloughed, and the patient died on the third day from septicæmia. The mortality, therefore, was 6 per cent.

Dr. THEODOR LANDAU (Berlin) held that in most cases it was not wise to wait too long before operating. The risks were: (1) sarcomatous degeneration of a simple myoma (of this he had seen three examples); (2) necrosis of the tumour owing to obliteration of the vessels by pressure, with resulting sepsis; and (3) exhaustion of the patient from loss of blood and consequent increased shock when it came to operation. It was a mistake to suppose that most fibroids became smaller at the menopause. He was pleased to find that Dr. Smyly was operating by the vaginal route and congratulated him on his results. If the surgeon wished to go in for a conservative operation and save the uterus, the vaginal route was well adapted for this and a speedy operator with thorough asepsis need not fear going on to do a ventral laparotomy if he were not able to finish by the vagina.

Dr. J. P. FARRAR (Gainsborough) read a paper on

A New and Speedy Method of Dilating a Rigid Os in Parturition.

He enumerated a series of cases on this subject of a very interesting nature. The new method was first brought to the notice of the profession at a meeting of the Obstetrical Society of London three years ago and the present paper was concerned with a detail of other fresh cases showing equally striking and remarkable results. Shortly, it was the application of a 10 per cent. solution of cocaine to the tin and unyielding os. In four minutes' time the physical change in the condition of the os was quite remarkable. Instead of a thin sharp margin—not unlike a piece of tin plate with a round orifice in it—the os became in four minutes' time widely open and as dilatable and distensible as a rubber bag.

Dr. JARDINE (Glasgow) had tried two-grain cocaine pessaries, but his results had not been very satisfactory. A solution might answer better.

Dr. ALICE KER (Birkenhead) spoke of the advantages of douches of very hot water in securing dilatation of a rigid os; they not only shortened the duration of labour, but also caused great diminution of the patient's sufferings.

Dr. A. DONALD (Manchester) read a paper on

Vaginal Section.

He gave the results of 60 cases in which he had opened the peritoneal cavity or operated for diseased conditions of pelvic organs by means of vaginal incision. The cases were classified as follows: exploratory incision, 18 cases; incision for pelvic abscess, 11 cases; incision for ectopic pregnancy, 8 cases; vaginal ovariotomy, 20 cases; and vaginal myomectomy, 3 cases. In 30 cases the incision was made in the anterior fornix and in the remaining 30 it was in the posterior fornix. Gauze packing or drainage was used in 25 cases. There were 2 deaths directly due to the operation, a mortality of a little over 3 per cent. The various conditions which might be treated by vaginal section were discussed in detail. The advantages of vaginal over abdominal section were summarised as follows: (1) absence of shock; (2) less risk of septic peritonitis; (3) quicker recovery and less troublesome convalescence; (4) avoidance of abdominal scar; (5) more perfect drainage; (6) better control of oozing of blood from pelvic cellular tissue or peritoneum; and (7) simplicity of procedure in some cases. All these points were considered in detail. The objections to the operation were then discussed. Narrowness of the vagina and pelvic adhesions occurring together formed a contra-indication to the operation, but either of these singly did not necessarily render vaginal incision very difficult. Mere bulk of a tumour, so long as it is cystic, was not a contra-indication, but a large tumour with adhesions at its upper portion could not be dealt with by vaginal section. The troublesome after-effects which were said to ensue through weakening of the pelvic floor had not been observed in any of Dr. Donald's cases.

Dr. W. E. FOTHERGILL (Manchester) contributed a paper on

The Function of the Decidual Cell.

Whilst investigating the ultimate fate of placental tissue retained *in utero*[1] Dr. Fothergill observed appearances which led him to believe that under certain conditions the enlarged connective tissue cells of the uterine mucosa—namely, the decidual cells—had a phagocytic action upon the fœtal epithelium covering the chorionic villi. The connective tissue cores of the villi also appeared to be destroyed by decidual cells, but much more slowly than was the chorionic epithelium. This action of the decidual cells under morbid conditions suggested to him that under normal conditions also the decidual cells might have a destructive action upon certain fœtal structures. He therefore examined a number of specimens of decidual and placental tissues obtained under circumstances as normal as possible in the hope that the above-mentioned pathological action of the decidual cells might afford a clue for the discovery of their physiological action. Villi which penetrated the decidua serotina were found to be without epithelium or to show only traces of it, while they were, as a rule, surrounded by numerous decidual cells; indeed, the tips of villi which had reached to and entered the surface of the decidua were found in all stages of disappearance, the stroma shrinking and vanishing more slowly than the epithelium. Sections cut through the membranes so as to show amnion, chorion, and decidua showed similar appearances. Those chorionic villi which were not in contact with decidual tissues retained their epithelium in a degenerated condition, while those embedded in the decidua were entirely without epithelial covering, the stroma also in many cases being reduced to a mere trace. Dr. Fothergill pointed out the importance of careful microscopic examination in every case in which the pregnant uterus was removed by operation, the main difficulty in settling questions of placental structure and function being the rarity of healthy specimens from the early months of pregnancy. It was generally admitted that at an early stage of development the chorionic epithelium had a destructive action upon the surface of the decidua. Dr. Fothergill's observations pointed to the conclusion that the decidual cells had in their turn, at certain stages of development, a destructive action upon fœtal structures. Thus in the formation of the placenta and membrane there occurred what may be broadly described as a struggle between fœtal and maternal elements which resulted in the destruction of both in considerable degree. The relation might be expressed in intelligible though somewhat inaccurate form by saying that the fœtus was a parasite and that the decidual cells prevented it from being an injurious parasite by attacking those fœtal structures which penetrated the maternal ones enclosing them. Viewed in that light invasions of the maternal organism by fœtal elements would be regarded as due to a failure to perform their duty on the part of the decidual cells. Dr. Fothergill's hypothesis thus possessed a general pathological interest as bearing upon the origin of certain neoplasms, besides giving an explanation of the existence of the decidual cell.

Dr. A. LAPTHORNE SMITH (Montreal) read a paper on

The Best Operation for the Cure of Displacements of the Uterus.

The conclusions to which he had come in his paper were based first upon his own personal experience of 111 ventro-fixations and 89 Alexander operations; secondly, upon the experience of 40 first-class operators, all Fellows of the American Gynæcological Society, who had had among them about 2500 ventro-fixations or suspensions of the uterus; and thirdly, upon his recent visit to the leading gynæcologists of Europe,

[1] Brit. Med. Jour., Jan. 29th, 1898.

Digitized by Google

whom he had seen performing vaginal fixation. His own experience with Alexander's operation was all that could be desired. There was no difficulty in finding the ligaments, no hernia, only one relapse, and no trouble in subsequent labours. With ventro-fixation the cases had been much more severe, because he had only done it when there were diseased tubes causing fixation of the uterus. One patient had died; 1 had relapsed; 1 had a hernia; 2 had had miscarriages, and 3 had had normal labours; in 7 cases a buried stitch had required removal subsequently. Out of the cases reported by other operators above mentioned there had been 146 pregnancies, in 36 of which there had been pain, miscarriages, or difficult labour requiring obstetrical operation, and two or three women had died. Most of these operators had abandoned fixation and now performed suspension by stretching round ligaments to the abdominal wall. As a result, however, of what he had recently seen on the continent he would now abandon both Alexander's operation and ventro-fixation and treat all these cases in future by vaginal shortening of the round ligaments which had the following advantages: (1) it was very easy; (2) it could be done very quickly; (3) it should have no mortality; (4) it was free from subsequent pain; (5) it would do as well for cases of retroversion with fixation as for those in which the uterus was freely moveable; (6) it did not interfere at all with subsequent labour or pregnancy; and (7) it did not leave any painful wound or unsightly scar, women being more willing to have an operation in the vagina than on the abdomen.

Mr. CHRISTOPHER MARTIN (Birmingham) read a paper on

The Conservative Surgery of the Ovary.

He pointed out the physiological value of the ovaries and urged the importance of saving even half an ovary in certain pelvic operations. In cystoma affecting only one ovary the other should not be removed. In sarcoma of one ovary, however, both should be removed. In inflammatory disease of the appendages on one side it was unnecessary to remove both sides. In cases of double pyosalpinx the diseased tubes with the uterus should be removed *per vaginam*, but one or both ovaries should be left behind. The section of the ovary was advised in some cases of fibroma, dermoid tumour, and cystic disease of the ovary. In cases of chronic and cystic ovaritis ignipuncture was recommended. In cases of parovarian cyst and cyst of the broad ligament the cyst should be shelled out of the broad ligament and the ovary preserved. Lastly, in cases of vaginal or abdominal hysterectomy one or both ovaries should be left behind.

STATE MEDICINE.

WEDNESDAY, JULY 27TH.

Dr. MACMARTIN CAMERON (Newton-Stewart) read a paper on

Surface Wells as a Source of Water-supply.

The Rivers Pollution Commissioners hold up the shallow or surface well to execration. In respect of wholesomeness, palatability, and general fitness for drinking purposes they form the time-honoured classification of potable waters into wholesome, suspicious, and dangerous, ranging from spring water in the top place to shallow well in the bottom place. But there are shallow wells and shallow wells—good, bad, and indifferent. He (Dr. Cameron) did not defend cesspools such as the Commissioners had in view, where the best title to the name of well consisted in the possession of a pump. Fortunately, such wells were less in evidence now than formerly. Subsoil water laboriously pumped or lifted by buckets from wells is being fast replaced by upland surface water distributed by gravitation. The main purpose of that paper was to ask whether that drastic and in most cases costly change was altogether reasonable, more especially when thrust upon unwilling and impoverished communities. It was only in the hope of eliciting the views of others that he had acted on the assurance of his friend Professor Hunter Stewart that such a subject would be likely to give rise to an interesting discussion. Reverting to the old classification of potable water Dr. Cameron maintained that the proper place of surface well water, if reasonably safeguarded, should be in the "wholesome" list, and that the list should read, "spring water, deep well water, upland surface water," with the addition of surface well water either before or after the third of those names. Everything depended on where the wells were situated and how the surroundings were protected. The fourth place on the Commissioners' table was allotted to "stored rain-water," but they would not have arrived at that conclusion solely from an inspection of backyard water-butts, with their customary mass of pollution. To place surface well water below that from cultivated lands was to neglect the essential difference between those waters—namely, that the well water underwent a more or less prolonged ground filtration. That fact was strongly insisted upon by Dr. Vivian Poore, the champion of surface wells, who maintained that contamination of such wells has always resulted from direct inflow of pollution from the neighbouring ground or by cesspool or sewer subsoil leakage. In some cases a farm is supplied with drinking water from a well in the centre of a pasture-field, and everything goes well. If, however, the field is then ploughed up and manured then the well becomes polluted. The danger arises when the turf is destroyed and an easy way made by the plough for the direct influx of polluting matter into the pipes or into the well itself. In two instances he had traced outbreaks of typhoid fever to the breaking up of the soil in that way. It is no uncommon thing for farmers to spread manure and dig potatoes on the very tops of these wells. In no single instance had he traced typhoid fever to any surface well situated in a decently clean locality. Typhoid fever was rare in his district, notwithstanding the fact that it contained outside the town a population of 40,000 or 50,000 persons dependent on surface wells. There appear to be an unreasonable distrust of surface wells and a blind faith in gravitation water. In the latter great attention was always bestowed on the sources, whereas surface wells are often placed in bad sites and under the worst possible conditions. Curiously enough, it is not uncommon to find a surface well yielding a pure water although uncased and exposed freely to contamination. With the approval of the Local Government Board a village in the county of Wigtown containing a population of nearly 1000 inhabitants will shortly be supplied with water from new surface wells dug in clean ground outside the village to replace polluted ones within. The alternative was a supply by gravitation from a burn three and a half miles away, a plan which would have entailed five or six times as much expense.

Professor HUNTER STEWART (Edinburgh) remarked that Dr. Vivian Poore's experiment with a 6 ft. well carefully cemented at the sides gave water which contained 7 micro-organisms to the cubic centimetre and bacillus coli was conspicuous by its absence. A part of the supply of the city (Edinburgh) was from wells near the Pentland Hills not more than 8 ft. deep, situated in highly manured land and exposed to pollution from neighbouring middens. From the water of these particular wells of a maximum of 8 ft. in depth he found a maximum of micro-organisms of 11 to the cubic centimetre and a minimum in 3 out of 8 wells of absolute sterility. These observations abundantly supported the observations of Dr. Poore.

Dr. NASMYTH (Cupar) said a surface well might be pure for instance on a hill side, but on the other hand it might be fouled. It was not the well but the circumstances which must be considered. The well would be right enough if we could get a pure zone round it.

A paper was read by Dr. R. SYDNEY MARSDEN (Birkenhead) on

Filaria Strongylus or False Tubercle in the Pig, Sheep and Goat.

This is a zoo-parasitical disease of frequent occurrence in the animals mentioned. Its description, however, was not to be found in any text-book on meat inspection. Dr. Marsden believed that lungs so affected were constantly seized and condemned as tuberculous. On examination the affected lungs might be slightly congested or even appear normal. The surface was covered with small light-brown or grey patches of from the size of a pin's head to that of a pea in the midst of small zones of congestion. The patches formed little raised tumours or granulomata resembling those of tuberculosis, but softer and more hyaline. They were scattered through the lungs and formed growths in section of the size of a farthing or a halfpenny. On taking them between the finger and thumb they were less firm and resistant than tubercle, and their size was not so great as a rule. On section they looked like tubercle with their hyaline grey appearance and the opaque yellow of their older and retrograde stages. On passing the finger over these growths a gritty feeling could be detected much resembling that of tubercle,

Digitized by Google

but less harsh. They appeared to be formed wherever an egg of the strongylus was arrested and became the centre of a granuloma. The structure exactly resembles that of tubercle—namely, giant cells, epithelioid zone, and small-celled external zone, but the distinguishing feature was the presence of one or more ova. The commonest sites of infection were the lungs, kidneys, and liver, and the best description of the disease is that given by Professor Boyce, its discoverer. As a practical conclusion Dr. Marsden pointed out that affected organs should be seized and destroyed, but the flesh of the animals was not affected. There was no emaciation and the brightness and "setting" qualities of the meat were not altered.

Dr. J. MCNAUGHTON (Australia) then read a paper on

An Epidemic of Typhoid Fever in Wimmera District, Australia.

The Wimmera district, north-west of Victoria, Australia, in 1893 suffered from an epidemic of typhoid fever. The water-supply was obtained chiefly from rain-water and ground tanks. Reservoirs were formed by impounding streams which supplied the tanks by gravitation. In 1888 Dr. McNaughton reported enteric fever to the authorities for the first time. At first the cases were mild but became more serious as the epidemic progressed. The chief preventive method was that of destruction by fire of all infective material.

THURSDAY, JULY 28TH.

By previous arrangement the Section of Psychology joined the Section of State Medicine in discussing two subjects.

Sir WILLIAM GAIRDNER, K.C.B., opened the debate on

Aphasia in Relation to Testamentary Capacity.

He said that aphasia had been little regarded from the physiological point of view, although from a clinical standpoint it reckoned an enormous literature. Besides Broca's convolution there were at least four other centres concerned in speech, to say nothing of a fifth or "ideation" centre, the location of which is still obscure. He would concede that a man who had never been otherwise than aphasic could never reach a higher level of reasoning than that of the dog or the horse, when a man became aphasic by accident, "lamed," as it were, theoretically he suffered some damage to his already developed reasoning faculties, but he was not prepared to admit that he suffered any derogation to his higher faculties. Pasteur had a right-sided lesion and made the short will, "I leave all my goods to my wife." Was his mental capacity diminished, or if the lesion had been on the left side would his will have been less valid? His (the speaker's) own view was that the existence of aphasia interfering with graphic or auditory speech threw the *onus probandi* upon those who wished to prove the genuineness of the will.

Dr. ELDER (Leith) believed an aphasic was necessarily on a lower mental and intellectual level, and in answer to a question said he believed Pasteur came under that general rule. It was difficult to say precisely where testamentary capacity ended. If the auditory centre were destroyed a person was unfit to make a will. Destruction of the graphic centre did not disqualify; the difficulty there was the legal formality; simple infra-pictorial visual and infra-pictorial motor aphasics are capable of valid will-making. In certain contingencies a will might be drawn up by "mirror-writing."

Dr. CLOUSTON (Edinburgh) said a vital point was whether the will was that of the patient or had been suggested to him. Aphasic patients would assent to anything, but it was the duty of a doctor invariably to put the alternative case to the aphasic testator.

Dr. MERCIER (London) opened the second subject by a paper on

The Plea of Insanity in Criminal Cases.

Medical men had no standard as to the mental condition which should exonerate a criminal from punishment. On the other hand, the principle was accepted that insane persons should not be punished with a severity equal to that inflicted upon the sane. While every insane person might commit offences for which he ought not to receive punishment, yet there were very few lunatics who were wholly irresponsible. He advanced the propositions that it was right and just to punish the insane for wrong-doing, and that to a greater or less extent that view was acted upon in every asylum, either directly or by the withdrawal of privileges. He urged medical witnesses not to shrink from asking total immunity for some criminals and partial immunity with mitigated punishment for others. To establish a plea of insanity proof of one or more of the following mental conditions should be demanded: delusions; such confusion of mind that the accused was incapable of appreciating in their true relations the circumstances under which the act was committed or the consequences of the act; marked inadequacy of motive; extreme recklessness and the non-concurrence in the act of the volitional self.

Dr. J. F. SUTHERLAND (Lunacy Commissioner, Scotland) said that in Scotland there was no desire among experts for an alteration in the law. He did not know any case in which injustice had been done where the plea of insanity had been advanced, but he knew instances of grave injustice where the offender was intoxicated. If any alteration of the law were required it was not as regards the delusional man but the intoxicated man who committed a crime of which he had little or no recollection. Intoxication was insanity of the purest kind and the habitual drunkard was not a voluntary drunkard. Such persons should not suffer for their crimes, although within the past five years in Scotland one such person had been executed.

Dr. BLANDFORD (London) urged that a lunatic's knowledge of right and wrong was that of an insane person, comparable to the recognition of the same kind by a child or a dog.

Professor GLAISTER (Glasgow) thought that the tendency was to do injustice not so much to insane persons as to the general public.

Sir WILLIAM GAIRDNER agreed with Dr. Mercier's propositions. To the two existing verdicts of "Guilty" and "Not guilty on the ground of insanity" he would add a third—"Guilty but insane."

Dr. MERCIER pointed out that there was another verdict in England—"Guilty, but strongly recommended to mercy"—which always influenced a court of law.

Dr. NASMYTH (Cupar) introduced a discussion upon

The Hygienic Control of Milk Supplies.

He first gave a summary of existing laws and of the systems in force in foreign countries. In view of the recommendations of the Tuberculosis Commission we might hope for better regulations. Legislation in Scotland was ahead of that in England since the Act of 1897 was passed and the notification of infectious disease became universally applicable to Scotland. It was now possible to localise outbreaks of infectious disease spread through the agency of milk and to take steps to prevent further spread. The great questions for the future were tuberculosis with reference to meat and milk and how the owners of tuberculous animals were to be compensated. The use of sterilised milk until tuberculous cows were eliminated was almost a necessity. The Legislature ought to take into account the fact that British farmers were forced to compete with dairy products produced in many instances under lax conditions. The home farmer might readily be placed in harassing competition with Danish and other producers who were not hampered with regulations.

Dr. SPOTTISWOODE CAMERON (Leeds) pressed strongly upon the Section the desirability of a sort of right of search or examination of milk farms even outside the city boundaries by the medical officer of health of the town into which the milk was brought. Enlargement of boundaries, to include largely the contributing farms, did something. Farms outside the borough might be as dirty as possible, but medical officers of health, although of course they visited such farms, yet had no right to do so. The authority should be able to act rapidly in the case of suspected dairies. In Leeds every infectious case was at once entered opposite the name of the supplying dairyman.

Sir CHARLES CAMERON (Dublin) said that twenty years ago he traced an extensive outbreak of typhoid fever in Dublin to the milk-supply. Recently they had ascertained the names and addresses of workers in dairies. The personal hygiene of such persons was insisted upon by such means as washing the hands and wearing blouses. The hawking and the storage of milk in rooms they attempted to check by registration. Compensation was given where milk was destroyed. Dairies should not be allowed to exist in crowded parts of towns.

Professor FORSTER (Strasburg) said that many pathogenic organisms could be killed by one minute's exposure to a temperature of 150° F. The bacillus typhosus was destroyed

Digitized by Google

by fifteen minutes' exposure to the same temperature, which did not spoil the flavour of the milk.

Principal DEWAR (Edinburgh) maintained that byres should be distinct from dairies or milk-houses. Scotch farmers would be willing if Government would offer full compensation to stamp out tuberculosis as they had done rinderpest. He did not imagine that any plan of notification of disease in animals would meet with any full results. He thought that the periodical inspection of dairies by veterinary surgeons must follow upon the reports of the Royal Commission.

Professor AITKEN (Edinburgh) advocated the use of milking machines which avoided the exposure of milk to air and to dirty hands. The personal hygiene of the workers should be looked after. Contamination of milk was in the main due to uncleanliness of environment of the milkers and their efforts should therefore be turned in those directions. It would be practical to have milking stalls close to, but separate from, the byres, fully exposed to light and kept perfectly clean. In such a place one would be able to obtain all the accompaniments which would enable milkers to extract the milk with the least contamination from air and other sources.

Dr. CHALMERS (Glasgow), without suggesting any doubt of the value of sterilising milk, raised a query as to its value as a recommendation to the general consumer. If, on the one hand, the consumer was told that by general control a pure milk-supply could be maintained was he not more likely to insist upon that being accomplished than by trusting to pasteurising which assumed an impure supply? With regard to the recommendation of the Tuberculosis Commission that certain diseases should be notified he thought affections of the teats should be included. In presence of so many unrecognised varieties of infectious disease he advocated the notification by the dairyman of all diseases whatever in the persons of his workers.

Dr. JOHN ROBERTSON (Sheffield) then read a paper on

Soil as a Factor in the Spread of Certain Diseases.

The renewed interest in soil as a factor in the spread of disease recalled the attention early given to that point by Budd, Simon, Buchanan, and others. With Dr. Gibson he had noted an upward growth towards the surface in bacillus typhosus. He had been led to believe that during the winter months the organism disappeared from the surface and remained sheltered in the deeper layers until it sallied forth again in the warmer season. From an examination of many yearly mortality maps some years ago he concluded that the disease constantly prevailed at a high rate in some districts and a low one in others. He had published elsewhere the observation that the typhoid organism died out during the cold months except when the soil was artificially fed with organic matter. That, in his opinion, explained to a great extent the local prevalence of enteric fever. The attention paid to the water-carriage of typhoid infection seemed to have distracted attention unduly from other methods of infection. He felt certain that dust was the chief agency in conveying the infection to man from the soil. The relative heaviness of bacteria was inferred from certain observations and experiments. If true, this fact goes far to explain why only persons coming within a certain area are affected, for it presupposes that such heavy particles will not travel great distances and is a further argument against aerial spread.

Dr. NEWSHOLME (Brighton) pointed out the extreme value of Dr. Robertson's experiments because they were carried out under natural conditions in the open field and not on sterilised earth.

FRIDAY, JULY 29TH.

Dr. REID (Stafford) presided in the unavoidable absence of Sir HENRY LITTLEJOHN.

Dr. F. T. BOND (Gloucester) opened the discussion upon

Vaccination, with Special Reference to Prospective Legislation.

There was no need, he said, in such an assembly to assume that all were convinced that vaccination was in some degree a protection against small-pox. Further that when properly performed it was free from serious risk, and that it was nearly, if not quite, as efficient a protection as an attack of the disease itself. In all legislation they must face facts and allow for differences of opinion. They had a right to ask Government to provide for revaccination, about which the present Bill was absolutely silent. There need be no question as to compulsory revaccination if a conscience clause were inserted. A parent objecting to have a child vaccinated at six months of age should have the opportunity of going before a court when the child was four months old to satisfy the justices of a conscientious objection. Any penalty then would be not for neglecting vaccination, but for failing to register the objection; and so it might be with revaccination. When an unvaccinated child, aged four or five years, was about to enter school the parents should attend a court and reassert the objection and again at the age of twelve years, acting on returns that could be obtained from the School Board. Parents who objected to having an infant vaccinated might consent in the case of grown children. These three attempts, however, would leave a certain percentage of unvaccinated cases, as would happen in this democratic country under any system. He suggested that private practitioners should be obliged to bring their standard up to that of the Local Government Board. Inspection might take the form of a few surprise visits and a prosecution here and there if necessary. Under the present Bill the sanitary authority would have as little power as now to promote vaccination and the medical officer of health would continue to have neither responsibility for, nor official connexion with regard to, one of the most important branches of his sanitary work. At the same time he (Dr. Bond) thought that there should be a public prosecutor to take up cases, which should be done judiciously. The Vaccination Bill was one of many illustrations of the increasing unfitness of Parliament, with its present antiquated regulations, to deal with the legislative requirements which the ever-augmenting complexity of our social organisation demanded.

Dr. MONCKTON COPEMAN (London) said that his experimental work, which was now accepted by the Government, had been in connexion with the purification and preservation of vaccine lymph. The use of glycerine was originated by an Englishman, W. Cheyne, in the year 1854, and was employed by Dr. Stephen Mackenzie and others during the epidemic of 1870–71, with the intention merely of increasing the stock of available lymph. He found large numbers of extraneous organisms in samples of human, and particularly in calf, lymph, some of them being indistinguishable from forms capable of setting up suppuration. In the course of work on the bacteriology of vaccine lymph he discovered a means of freeing lymph from such organisms. After many experiments he found that glycerine had the power of killing out those extraneous organisms after a certain definite time and if used under certain definite conditions, while at the same time the efficiency of the lymph was uninjured. It was proposed to use lymph only which had been shown by the method of plate cultivation to be free from micro-organisms. In the future possibly something better than glycerine might be found. At present when rightly used it was the only substance which was capable of giving results of value in the purification of lymph. Unfortunately vendors were now selling "glycerinated" lymph which did not answer to his own definition of a carefully tested and aseptic vaccine lymph.

Dr. NEWSHOLME (Brighton) hoped for the withdrawal of the Bill for a time in order to get a fuller expression of popular opinion. He moved the following resolution:—

That in the opinion of this Section the Vaccination Bill before Parliament should be withdrawn in order that the Government might have the opportunity of fully considering the views and facts which have emerged in the discussion upon the Bill on the part of the profession and the public and that a new Bill should be introduced next session.

Dr. C. R. DRYSDALE (London), in seconding the resolution, held that vaccination and revaccination should be carried out by animal, and not by humanised, vaccine. During the last century small-pox was a children's disease and rarely killed adults. Nowadays in this country it was fatal almost entirely in adults over the age of twenty years. Since 1875 Germany had vaccinated every infant and revaccinated every child before the age of thirteen years. The success of that experiment was shown by Gerhardt, who wrote in 1896 that the disease had almost died out in Prussia.

Dr. G. C. FULTON (Middlesboro') and Dr. C. SMITH addressed the meeting and Sir WILLIAM PRIESTLEY announced that the Bill would come before the House on the following day (Saturday).

The resolution was carried and copies were directed to be sent to the leaders of both Houses of Parliament and to Lord Lister.

Sir CHARLES CAMERON (Dublin) in opening the discussion on Dr. J. Robertson's paper on

Soil as a Factor in the Spread of Certain Diseases,

said that in Dublin a close relationship existed between the soil and the existence of typhoid fever.

Digitized by Google

Sir RICHARD THORNE (London) remarked that two years ago he asked the Government to take steps in that direction because of the constant recurrence of typhoid fever when it had once entered any particular spot. Experiments showed that the bacillus typhosus flourished well in soils which contained the bacillus coli but infinitely better in the presence of bacillus enteriditis sporogenes. He hoped that the question of tuberculosis and soil would be investigated. He trusted that in this country they would never fall into the error of regarding the bacteriological laboratory as the *summum bonum* of public health work. Much of our best preventive work had been effected in pre-bacteriological days. Bacteriology was a precise and scientific science, but it was by its practical application that the medical officer would hold his own.

Dr. H. SCURFIELD (Sunderland), who came from a town in which typhoid fever was very prevalent, had noticed how year after year the disease had clung to infected houses.

Dr. F. J. ALLAN (London) read a paper on

Formaldehyde and Sulphur as Disinfectants,

which contained the following conclusions:—1. Sulphur dioxide killed the diphtheria bacillus easily, the shortest exposure being 4½ hours to air in which 1 lb. of sulphur per 1000 cubic feet had been burned. Cholera bacilli were killed in the dry state in air by the combustion of 2½ lb. of sulphur to 1000 cubic feet. Anthrax and typhoid fever bacilli were not killed by this gas. 2. Formic aldehyde. Trillat's autoclave proved unsatisfactory. The Alformant lamp gives good results and kills diphtheria and typhoid fever organisms, moist or dry, after 6 hours in air charged with 10 "paraforms" per 1000 cubic feet.

Dr. KENWOOD (London) was glad to hear that Dr. Allan's experiments agreed with his own. One important fact was that if the Alformant lamp was to be effectual it would be necessary to employ more of the paraform tablets than were recommended by the manufacturers. He found that ten "paraforms" simply inhibited organisms of slight resistance. He concluded that twenty-five should be used per 1000 cubic feet to ensure disinfection.

Dr. LESLIE MACKENZIE (Leith) stated that for over two years he had used formalin spray and that he had ceased to use gaseous disinfection because he found that the spray was more simple and more rapid. He had disinfected many houses for various infections and never in one single instance had he found any case traceable to the disinfected room. The chief practical objection that at first caused him to delay the adoption of the spray for general disinfection was its possible effect on walls and wall-papers. He exhibited specimens of variously coloured papers which had been pasted on boards and then sprayed to saturation. None showed the slightest damage.

Dr. F. A. DIXEY (Oxford) read a paper on

Diphtheria in London.

His main conclusions were that the interruption to the usual course of diphtheria mortality coincidently with the two chief school holiday periods was apparent both in 1896 and 1897. This tended to confirm the importance of school infection. A considerable number of cases were still returned as croup. The marked diminution in the case mortality which began in 1894 had been maintained and was coincident with the introduction of the treatment by antitoxic serum.

Dr. MILLARD (Birmingham) read a practical and interesting paper on

"Return" Cases of Scarlet Fever.

Sir CHARLES CAMERON, chief medical officer of health of Dublin, read a paper on

The Incidence of Private Improvement Expenses in relation to Rack-rent.

He pointed out that the improvements in the sanitary conditions of houses involving structural alterations had to be paid for by the immediate rack-renter. This rent was defined in the English Public Health Act to be the bare rent of premises, minus the sum necessary to keep the premises in repair and some other deductions, the whole to be determined by the Court. The Irish definition was more simple and was a better one—namely, two-thirds of the valuation of the premises for rateable purposes. If a house was valued at £90 a year and was let at £60, then the latter was a rack-rent. Sir Charles Cameron pointed out that it was often unfair that the person who received a rack-rent should pay the cost of the improvement. He might have let the house on a lease for ever, or he might pay a rack-rent greater than the rack-rent which he himself received. He quoted the case of a man who let his house for twenty-one years and who eighteen years afterwards became the yearly tenant of his own tenant. He complained of the bad drainage of the house and on the sanitary authority intervening the immediate rack-renter was obliged to pay the cost of improved drainage and sanitary accommodation, though in three years the house would revert to the present yearly tenant. After describing several cases of injustice Sir Charles Cameron suggested an amendment of the law so that all the persons having an interest in sanitary improvements should contribute proportionately to the cost.

Dr. H. SCURFIELD (Sunderland) then read a paper on

The Necessity for the Amendment of Part I. of the Housing of the Working Classes Act, 1890.

He thought that Part I. of the Act would be of much greater value if the preliminaries of a scheme were simplified and powers were given to the local authority to decide on the type of buildings which were to be erected on the "unhealthy area." At present the preliminaries were so drawn out as to exhaust the energies of the most ardent sanitary reformer. In Sunderland it was proposed to deal with an area of about half an acre, with 480 inhabitants. A representation was made by the medical officer of Health in August, 1893. The scheme was completed and advertised in October, 1893, and forwarded in November to the Local Government Board, who held an inquiry in January, 1894, and issued a provisional order in May, 1894. In September, 1894, the same board held a second inquiry. In 1896 the purchase of properties was so far completed as to warrant an advertisement for designs for workmen's dwellings. The prizes for that competition was awarded in January, 1895. The accepted plans were then slightly amended and provisionally approved in March, 1897. Various transactions with the Local Government Board, including an extension of the original scheme, ended in a deputation to the latter in December, 1897. Further amendments were approved by the council and were forwarded in February to the Local Government Board, who asked for further plans, which being approved they ordered a further local enquiry in July, 1898. Four years and eight months had thus elapsed since the original petition was made, and there was still no prospect of an early start. Dr. Scurfield advocated an amendment of the Act by leaving the kind of buildings to be erected to the discretion of the local authority, and by simplifying and shortening the preliminaries of such improvement schemes.

Resolutions.

Dr. M'LEAN WILSON (Wakefield) proposed the following motion:—

That in the opinion of this meeting (1) further legislation for the prevention of river pollution is urgently required, lengthened experience having shown that the Act of 1876 is in many respects defective; (2) that the Bill at present before Parliament is insufficient and unsatisfactory; and (3) that the parliamentary Bills Committee of the British Medical Association should take action in the matter.

Dr. ALFRED HILL (Birmingham) seconded the motion, which was adopted.

Sir CHARLES CAMERON proposed a second motion which was as follows:—

That in the opinion of this Section a standard percentage of fat should be fixed for milk, but it should not go so far as to say what that percentage should be.

Dr. ALFRED HILL seconded the motion and it was adopted.

Dr. SCURFIELD proposed the following motion:

That it be a recommendation to the Council that in future meetings of the Association there be a separate section for public health.

Dr. KENWOOD seconded the motion, which the section adopted.

A vote of thanks was then passed to the President, Sir Henry Littlejohn, and the proceedings came to a close.

NEUROLOGY.

FRIDAY, JULY 29TH.

Demonstration of Specimens.

The meeting on this occasion was devoted to the demonstration of specimens.

The first was by Dr. I. C. DUNLOP (Edinburgh) and Dr. GEORGE MACKAY (Edinburgh) to illustrate the condition found in the Brain of a patient who had suffered from Defect in Colour Vision.

Dr. JAMES TAYLOR showed with the lantern specimens

Digitized by Google

illustrating the Changes in the Spinal Cord associated with Anæmia and Allied Conditions.

The PRESIDENT showed Photographs of the Brain of a patient who had lost the Naming Faculty.

Dr. A. W. CAMPBELL also demonstrated with the lantern various interesting Conditions occurring in Brain and Spinal Cord, among others the sclerosis found in some cases of anæmia.

Dr. E. F. TREVELYAN (Leeds), Dr. MICHELL CLARKE (Bristol), Dr. A. BRUCE (Edinburgh), Dr. R. A. FLEMING, and others also showed collections of very interesting pathological specimens.

PATHOLOGY.

THURSDAY, JULY 28TH.

Dr. HERBERT E. DURHAM (London) read two papers on: (1) an Inquiry into an Epidemic caused by a Variety of the Bacillus Enteriditis of Gärtner by Means of Sero-diagnosis (Gruber's Reaction) and Bacteriological Examination; and (2) on a Simple Method of Demonstrating the Formation of Gas by Bacteria.

Dr. LAZARUS-BARLOW (Cambridge) read a paper on Irritation of the Pleura and Pleurisy and showed a number of lantern slides in illustration of his results.

Professor GREENFIELD (Edinburgh), Dr. WOODHEAD (London), Professor MCFADYEAN (London), Dr. MUIR, and Dr. D. A. WELSH (Edinburgh) criticised the paper, and Dr. LAZARUS-BARLOW replied.

Dr. DURHAM then opened a discussion on

The Agglutinating or Sedimenting Properties of Sera and their Relation to Immunity.

He said that the importance of the agglutinating principle had been greatly enhanced by the observation that the blood serum of typhoid fever patients might acquire the property of clumping cultures of the typhoid bacillus. This observation was first made in the Hygienic Institute of Vienna by Dr. Grünbaum working at the suggestion of Professor Gruber. As the known varieties and species of bacteria were steadily increasing it became more and more difficult to find criteria by which the different kinds might be distinguished. The principle of specific immunity thus became of the greatest importance and might be applied in three ways: (1) in respect of the protective power of a serum; (2) in respect of its lysogenic power; and (3) in respect of its agglutinative power. Many writers have denied the existence of any relation between agglutinative and protective action, and it was well known that certain forms of protective sera had no agglutinating power—e.g., diphtheria antitoxin serum. Agglutinating properties were therefore not essential to protective sera. The problem, however, was rather in the opposite sense—viz., whether the agglutinating property was always associated with some degree of protective power. Pfeiffer endeavoured to discredit the existence of any relation between these two properties on very insufficient grounds. He found that several months' after a Haffkine cholera injection the agglutinating power had fallen to the level present in many normal sera, while the protective power was still considerably increased. His results showed that a complete lysogenic action occurred only in those cases in which a dose of serum approaching the limit of clumping effect was given; unfortunately the condition of the vibrios immediately after injection was not stated. His other experiments with old sera merely showed that low protective and destructive (lysogenic) powers were associated with low clumping power. Pfeiffer's test reaction was not necessarily associated with a complete protection. In reality the destruction of the bacteria introduced was only partial at the end of the time limit, for if the animal be killed when all the organisms in the peritoneal fluid were degenerated numerous untransformed individuals were found on the omentum. In all probability the previous agglutination of the bacteria was an important factor in the production of the degenerative process in the free peritoneal fluid. According to Dr. Durham's own observations on sixteen different vibrios a positive Pfeiffer's reaction (lysogenic properties), a complete sedimenting effect and permanent protection were invariably associated. Other observations made by Dr. Durham on the action of sera obtained from patients in an epidemic associated with the presence of a variety of the bacillus enteritidis were in harmony with the view that protective and lysogenic properties were associated with agglutinins. It was interesting to note that even with a non-pathogenic organism an agglutinative serum might be obtained. Thus after injection of the bacillus megatherium a serum might be obtained which had the power of sedimenting this bacillus and typical degeneration occurred when tested by Pfeiffer's method. The question arose whether there was any evidence of a proportional relation between the protective and the clumping power of a serum. It was essential to note that the less virulent races of vibrios were more susceptible to the agglutinins produced by the use of virulent varieties than were the virulent varieties themselves. Moreover, the serum obtained by means of the less virulent, though highly effective on them, had slight influence on the more virulent kinds. Again, everyone who had watched the process of agglutination under the microscope must have observed that some individuals were affected long before others, while a few might escape altogether. If, then, the agglutinating power of a serum be measured by the limit dilution at which a visibly recognisable effect was produced in a given time we got some idea of the action upon the susceptible individuals, but the resistant and less susceptible organisms were not heeded. Hence in contrasting the protective and clumping efficiency of sera we must take into account the effect produced upon the more resistant as well as that upon the more susceptible individuals. When bacteria were grown in the presence of even small quantities of efficient agglutinating serum they exhibited departures from their normal habit of growth—e.g., the reducing power of a cholera vibrio might be checked, the phosphorescence of a luminous vibrio might be stopped, the production of the pigment pyocyanin by the bacillus pyocyaneus might be inhibited, and there might be a tendency to grow in threads or chains by microbes which did not naturally present this feature. No one had yet succeeded in separating out a pure agglutinin, so that it was impossible to say whether these inhibitory actions were due to the agglutinins themselves or to substances associated with them. The fact of this association, however, was extremely suggestive.

Professor MCFADYEAN (London) congratulated Dr. Durham on the extremely able manner in which he had dealt with a difficult subject. He thought that it was not only of laboratory interest but it had a wide clinical interest as well.

Dr. GRÜNBAUM (London) said that he had worked chiefly on sera from the human subject, the agglutinative action of which was often small. He thought it was important to note that in low dilutions the agglutinative property did not necessarily go hand in hand with the protective power. He suggested that a fourth specific property of the serum of an immunised animal might be added to those mentioned by Dr. Durham—viz., a paralysing action. This was especially noticeable in the case of motile organisms, but even non-motile organisms might show loss of Brownian movement—probably by a swelling of their envelope in the specific serum.

Professor MCWEENEY (Dublin) said that he, too, had worked only on human sera. He suggested that a fifth serum reaction might be added—viz., a concatenating action. He had come to the following conclusions from a study of typhoid bacilli grown in broth containing typhoid serum: (1) there occurred loss of motility; (2) there was a tendency to the formation of short chains of bacilli; (3) this method was suitable for clinical diagnosis; and (4) it was of special value in those cases in which the ordinary Gruber-Widal clumping reaction was delayed or uncertain.

Dr. SIMS WOODHEAD (London) said that in these sera there appeared to be a number of actions which ran parallel to a certain extent and later diverged. He had already stated in this section that the toxins were by no means such simple bodies as were at one time supposed and they had just heard that the sera were equally complicated. He pointed out that the sera which were most highly protective—e.g., tetanus and diphtheria—were less agglutinative; and he regretted that the highly agglutinative sera—e.g., cholera and typhoid—could not be raised to such a degree of immunising activity. He agreed, however, with Dr. Durham, as against Widal, that a high agglutinative power in either cholera or typhoid could hardly be associated with a low immunising power.

FRIDAY, JULY 29TH.

Dr. ALFRED G. LEVY (London) read a paper on the

Blood Changes after Experimental Thyroidectomy.

He said that his experiments had been performed on the dog so that the parathyroids and thyroids were removed together, and suggested that the variations which occurred in his

Digitized by Google

results might be due to the presence of small accessory thyroids in the region of the aorta. He found that there occurred after thyroidectomy a certain degree of anæmia, which, however, was neither very intense nor very constant. The red corpuscles and the hæmoglobin were diminished together, but the total fall did not exceed 25 per cent. of the normal. In the more pronounced cases the liver gave a slight iron reaction. Leucocytosis was a very constant feature, but the degree varied enormously. Increase of the fibrin of the blood invariably occurred and was often very considerable. The proteids and the total nitrogen also underwent diminution. The total solids were always reduced. In most instances the loss of solids was greater than the loss of proteids, but sometimes the loss of proteids was the greater. These facts appeared to point to a varying loss of some and a varying gain of other non-proteid material. Throughout these experiments careful attention was given to the housing and feeding of the dogs so that no fallacy might thereby be introduced. In conclusion, he referred to the striking want of interdependence among the various blood changes and to the fact that they bore no relation to the rapidity of onset or the severity of the symptoms.

Dr. D. A. WELSH (Edinburgh) said that although he had never examined their blood during life he had observed in animals dying from removal of the parathyroid glands alone that the tissues and organs were often anæmic and showed evidence of commencing fatty degeneration.

Dr. MOTT (London) suggested that the tendons and the connective tissues of the body should also be examined in relation to these blood changes.

Dr. MUIR said that he had examined the blood in cases of myxœdema in man and had found a slight degree of leucocytosis, but the condition of the leucocytes was variable.

Professor RALPH STOCKMAN (Glasgow) read a paper on

The Pathological Effects of Dead Tubercle Bacilli.

He said that he had had three objects in view—(1) to compare the effects of dead with those of living bacilli; (2) to see if fibroid changes were especially produced by the dead organism; and (3) to find whether animals injected with dead bacilli would still react to tuberculin. His first experiment was on a healthy dog; it was injected with tuberculin and no reaction occurred. An injection was made into the jugular vein of about 50 c.c. of a glycerine broth culture of tubercle bacilli which had been sterilised at 110° C. A rapid rise of temperature occurred, which continued for some days. Seventeen days later, when the temperature had subsided, tuberculin was injected, but the reaction was slight and indefinite. When the animal was killed, four months after the intravenous injection, the pleura was found to be studded with small fibroid nodules and the liver showed a large number of small tuberculous masses in its substance. His second experiment was on a pony. Having been tested with tuberculin with a negative result it received into its jugular vein a similar enormous dose of dead tubercle bacilli. The immediate effect was a marked rise of temperature for about a week. Three weeks later the tuberculin test gave a distinct reaction. The animal was then killed and the lungs were found to contain very numerous small tuberculous nodules, which consisted chiefly of a connective tissue overgrowth with few giants cells and no distinct caseation. Numerous bacilli could be demonstrated in these nodules by the ordinary method of staining. The other organs showed no tubercle. The third experiment was on a number of cats which were fed on dead tubercle bacilli in order to see if any lesion could be produced through the alimentary tract. No tuberculous lesion, however, was found in any organ, though the animals had been allowed to live from one to two months.

Professor J. R. MCFADYEAN (London) said that these experiments were of considerable interest, but he did not think that they had any intimate relation to the processes of tuberculosis naturally occurring in animals. He had never experimented with such colossal doses of bacilli and he believed that no lesions followed the injection of dead bacilli unless enormous doses were given. He did not think that the formation of giant cells was so closely related to processes of caseation as Professor Stockman had maintained, for caseation was a result of living organisms alone.

Dr. SIMS WOODHEAD (London) said that he had investigated the effects of injecting dead bacilli and had found that dead bacilli locally injected produced a local lesion in which the bacilli could still be stained but from which no secondary infection could be obtained. Intravenous injection of dead bacilli produced numerous fibroid nodules chiefly in the lungs. He pointed out that similar injections of living bacilli in guinea-pigs produced caseous tubercles in the lungs, but that with devitalised bacilli fibroid non-caseating lesions occurred. He had also found that if the injection were made into the thigh then fibroid tubercles might appear not only in the lung but in the liver.

Professor GREENFIELD (Edinburgh) said that all the previous speakers seemed to have acknowledged a possible flaw in their experiments and he suggested that it was just possible that some of the bacilli injected as dead might be still living. Undoubtedly, however, dead bacilli seem to be capable of producing elementary tubercle follicles with giant cells. In regard to the occurrence of nodules in the liver after intravenous injection he thought it quite possible that dead bacilli might pass through the pulmonary capillaries and so reach the liver.

Professor MCWEENEY (Dublin) suggested that the virulence of the organisms should be determined before they were devitalised. He thought that the same result could hardly be expected to follow the presence in the tissues of virulent and of attenuated organisms even though they had previously been devitalised.

Dr. MOTT (London) suggested that inoculation of the fibroid nodules produced by the action of devitalised bacilli should invariably be performed.

Dr. J. J. DOUGLAS (Edinbugh) read a paper on the Local Action of Crude Diphtheria Toxin and illustrated his results by a series of lantern slides from photomicrographs. Dr. MUIR and Dr. LAZARUS-BARLOW spoke.

Dr. S. R. CHRISTOPHERS (London) read a paper on the Action of Normal Serum in Relation to the Diagnosis of the Typhoid Bacillus.—Professor MCWEENEY described some work he had done on the same subject.

Dr. ALEXANDER HAIG (London) gave a Demonstration of the Granules precipitated in the Blood by Chloride of Ammonium. He maintained that the number of these granules varied with the quantity of uric acid passing in the urine.

PHARMACOLOGY AND THERAPEUTICS.

FRIDAY, JULY 29TH.

Professor RALPH STOCKMAN (Glasgow) introduced a discussion upon the

Therapeutic Value of Recent Synthetic Analgesics: Their Benefits and Later Attendant Risks.

Most of these preparations, he said, had been introduced to us not so much as analgesics but as antipyretics. But long experience had demonstrated that medicines which merely reduce temperature had comparatively little beneficial effect on the course of a continued fever such as typhoid, and as a routine treatment they had practically been abandoned. The direct antipyretic treatment of feverish conditions had also to a great extent gone out of fashion owing to the more specific treatment by serum therapeutics. But in diseases marked by great pyrexia, such as acute rheumatism and malaria, the combination of an analgesic and antipyretic with a specific such as salicylate or quinine respectively was of great value. It was more directly to their value as analgesics that Professor Stockman directed attention. No one member of the group acted in an ideal way either in reducing temperature or in relieving pain. The drawbacks and dangers had been exaggerated. Still, no one was without more or less serious drawbacks for general and frequent use in practice. Their chemical genealogy was studied as being the best way of leading up to their remedial and poisonous actions. All were closely allied to phenol and to anilin. By a chemical modification of these two bodies we were able to lessen their toxicity and to increase their analgesic action. But we could not yet prophesy what the value or action of a combination would be without long trial. Tables of graphic formulæ were exhibited illustrating the close chemical relationship of these bodies. In doses ordinarily given phenol had very little effect on the blood or nervous system, but large doses had poisonous effects. The toxicity of salicylic acid in ordinary doses was almost *nil*, but very large doses set up skin eruptions and other undesirable symptoms. When we came to anilin we found its medicinal use was dangerous, its action on blood causing cyanosis and dyspnœa. Phenylhydrazin caused thrombosis in vessels and was a strong poison. Pyrodin was impossible

Digitized by Google

as a therapeutic agent. All had the same kind of action on the grey matter of the spinal cord: conduction of painful impressions was lessened and perception of impressions in the grey matter of the brain was lessened. To these actions was the analgesic effect due. Because of the absence of their action on the motor centres the person could go about his business and herein lay their great value over opium and chloral. We were in want of two drugs, one to act on the pain-conducting paths of the cord and another to act as a hypnotic on the cerebrum. Drugs, like men, had the defects of their qualities. Their depressing effects might lead to respiratory and cardiac embarrassment. Collapse from a direct action on the nervous system was extremely rare and only occurred in the debilitated. We should never get a drug quite free from this, for it depended on the sensibility and reaction of the individual. We could diminish the chance of collapse by using a drug which was not too active. In seeking an analgesic drug from amongst the enormous number of candidates for therapeutical favour we should reject those which had destructive action on hæmoglobin. It is fortunate that in practice they had these poisonous qualities only in small degree. Professor Stockman had given up the use of acetanilid because of its action on the blood and because of the small range of its dose. There was no doubt that when it was introduced it was given in much too large doses. Antipyrin was much safer, but he seldom gave it now. Phenacetin was equally powerful and much less apt to be attended by danger. It was much the safest and best and he had never seen the slightest degree of faintness or unpleasantness result. The only other member in which he placed confidence was lactophenin, which was practically identical in composition with phenacetin. Antithermin was distinctly poisonous and was not a substance to be used at all. In conclusion, Professor Stockman said that if given with care any ill effects were infrequent and that it was a matter largely of dosage.

A paper by Dr. C. D. PHILLIPS (London) (read by the SECRETARY) followed in which he classified synthetic analgesics into three main divisions—viz., those derived from: (*a*) chinolin; (*b*) anilin; and (*c*) salicylic acid. Analgen, a chinolin derivative, was not a powerful analgesic agent. Its great evil was its destructive action on the red blood corpuscles. Euphorin was a powerful analgesic; it tended to interfere with the respiratory process, it did not affect the kidneys, and it was valuable in the pain of orchitis. Methylene blue was a useful analgesic in all forms of headache; it often, however, caused cystitis and strangury. Pyoktanin was of little value. Agathin was unreliable and even increased pain; it was unworthy of a place. Pyramidon, salipyrin, tolipyrin, tolisoll, and ferripyrin were harmless, but were not sufficiently powerful for the relief of urgent pain; they were, therefore, unimportant. Malakin was slow in action and was much inferior to antipyrin; it was of service in acute rheumatism and was free from risk. Neurodin was feeble and harmless, but it was uncertain and inferior to phenacetin and antipyrin. Lactophenin was sedative more than analgesic; it was inconstant and often failed. The action of citrophen was much the same as that of phenacetin, but the risks were greater and the benefits were less; it ranked much below phenacetin. Apolysin was more toxic and more soluble than phenacetin, it was of great value in migraine and was well tolerated in large doses. If taken on an empty stomach, however, its toxic effects were specially liable to occur. Phenocoll was a powerful analgesic but not so safe a remedial agent. In children and in adults with phthisis it caused alarming cyanosis; in the future it might, however, take a place. Salocoll caused no gastric irritation. Salophen was probably the best of recent synthetic analgesics. Like salol it was not decomposed till it reached the intestine, its toxicity was very slight and in medicinal doses it did not produce tinnitus. It was good in neuralgias of children and was as effective and as safe as antipyrin and phenacetin. Salophen was thus of high value and of great promise. Agathin was to be avoided. One should hesitate to use analgen, citrophen, euphoren and lactophen. Pyoktanin, pyramidol and salocoll were unnecessary.

Dr. LOCKHART GILLESPIE (Edinburgh) pointed out the great benefit to be derived from adding caffein to these analgesics to prevent depression of the heart.

Professor LEECH (Manchester) said that a list of analgesics like that given afforded hope that we might yet obtain a substance better than any of those and so be able to relieve pain without doing any harm. He believed there was very little good in many of them and that dreadful mistakes were made in the dosage. Some of the evils put down to the drug were simply the result of accident and were not due to the drug at all. Professor Leech had no fear of antipyrin; he considered it useful in relieving pain and that it was harmless. Pyrodin was a most fatal drug. As to exalgin, much evil was seen in large doses but not in moderate ones. Antipyrin and phenacetin were so far, he considered, the best yet introduced.

Dr. LIDDELL remarked that he used exalgin without unpleasant symptoms and that antipyrin added to the great depression of influenza. He said there was great need for a local anæsthetic for the skin for the use of the dermatologist and that there was a field open to experimentalists in that direction.

Dr. HAMILTON (Hawick) had never used phenacetin or antipyrin without citrate of caffein. He considered that the deaths of many patients who died from heart-failure in influenza were actually due to the action of phenacetin and antipyrin. Much of the fear in many was due to want of knowledge of doses and most of the list of analgesics should be expunged.

Dr. GORDON did not agree with Professor Stockman in throwing cold water on antifebrin and exalgin. He advocated the use of small doses to begin with and by gradually increasing them danger was prevented. We were apt to attack pain from one specific point and forget that neuralgia might depend on more than one condition. He found antifebrin in doses of from ½ to 1 gr. give splendid results in painful malaise in children and from 1 to 2 gr. doses of exalgin he used with benefit in localised neuralgia such as toothache, also in locomotor ataxia. Antipyrin should always be guarded by caffein citrate in 2 or 3 gr. doses. He had seldom seen any untoward effects from the use of antipyrin, but the promiscuous employment of this drug by the laity did much harm. Phenacetin he considered distinctly beneficial and he thought that this drug and antipyrin were our most important remedies for pain.

Dr. FREW used antipyrin largely in children's diseases and antifebrin also very extensively, because its action was not more dangerous than that of antipyrin, while for working-class practice it had the advantage of being much cheaper than antipyrin. The knowledge of the dose he thought the chief point in preventing injury; the condition of the patient ought always to be considered before giving large doses. The combination with caffein might do harm in cases of high tension.

Dr. AFFLECK (Edinburgh), President of the section, said the frequency and importance of the use of these remedies was a sufficient reason for a discussion of them. Unfortunately they were largely used by the public irrespectively of medical advice. At the beginning of an acute illness these drugs were often taken by patients without consulting a medical man and thereby a bias in a wrong direction was given to the course of the illness. He thought there was really no danger in these remedies if given with due care and that it was largely a matter of individual experience, prejudice, and liking. Untoward effects appeared occasionally—e.g., in advanced phthisis. Of their value as pain-relievers there was no doubt—e.g., exalgin in cancer of the stomach. As regards analgesic effects he was apt to favour phenacetin because he had seen no ill-effects after its use. Much depended on the directions given; the sedative effect was largely increased by repose; the patient should not go about. The most important effect of salicylic acid and its compounds was the relief of pain; the delirium which sometimes followed its use was probably due to idiosyncracy and therefore great watchfulness should be exercised.

Professor STOCKMAN, in reply, said that when any of these new bodies containing phenol and anilin were introduced they should be regarded with great suspicion till they had been well tested. As to caffein, it produced high tension and a stimulation of the cerebrum and probably of the cord and should not be employed in routine practice. There were many complaints in the profession as to the large number of analgesics thrown on the public. Acetanilid must be given in small dose and carefully. It was not a drug to be given freely and frequently in practice. As a local analgesic we must still be content with ethyl chloride and cocaine.

Mr. J. C. MCWALTER (Dublin) read a note criticising the

Digitized by Google

New British Pharmacopœia and deploring what he termed the "secrecy" maintained in its production.

Professor LEECH (Manchester) and Dr. TIRARD (London), both members of the Revision Committee of the Pharmacopœia, replied, alleging that the criticism was based on an imperfect appreciation of the law under which the Pharmacopœia had to be issued.

LARYNGOLOGY AND OTOLOGY.

FRIDAY, JULY 29TH.

The Pathogenesis and Earlier Clinical Evidence of Laryngeal Tuberculosis.

A paper on this subject was read by Dr. W. JOBSON HORNE (London), and a lantern demonstration of microscopic specimens was given which showed how the larynx became infected, the origin and formation of giant cells, and the changes which occurred in the blood-vessels and muscles in the commencement of the disease. The lantern photographs left no doubt as to the accuracy of the explanation offered. Dr. Horne indicated the signs and symptoms which he regarded as the clinical counterpart of the morbid changes noted in the tubes, and which he considered of value in arriving at an earlier diagnosis, not only of laryngeal tuberculosis but also of pulmonary tuberculosis.

A discussion ensued, in which Dr. TILLEY (London), Dr. ST.CLAIR THOMSON (London), and Dr. MILLIGAN (Manchester) took part.

The following papers were also read and discussed in this Section:—

Dr. WALKER DOWNIE (Glasgow): Three cases of Foreign Bodies in the Throat, in which the position of the body was determined by the Roentgen rays. Illustrated by skiagraphs.

Dr. ADOLPH BRONNER (Bradford): A Plea for a more efficient Sterilisation of Nose and Throat Instruments. Dr. Bronner indicated the danger of infection from case to case, and demonstrated an apparatus he had designed for sterilizing throat-mirrors and other throat instruments.

Dr. HAMILTON BALLANCE (London) reported a case of Lateral Sinus Pyæmia occurring in a young married woman during her first pregnancy, the clinical features of which were rigors, operation, jaundice, delivery, and tonsillitis (the tonsillar abscess was opened under cocaine), attended with severe symptoms of cocaine poisoning; further rigors, facial erysipelas (which was treated with injections of 20 c.c. of streptococcus serum antitoxin), pyæmic abscesses in calf, shoulder and kidneys; serum repeated; recovery. Dr. Ballance attributed the recovery in some measure to the streptococcus serum. In the discussion which followed, Dr. BARR, Dr. MILLIGAN, and Dr. HORNE took part and mentioned the importance and value of rigors in arriving at a diagnosis in this form of ear disease.

Dr. ST.CLAIR THOMSON (London): Nasal Hydrorrhœa. The paper went to show that several reported cases of nasal hydrorrhœa were not such. The diagnosis could in great measure be decided by the nature of the fluid.—A discussion ensued and supported this view.

Dr. J. MIDDLEMASS HUNT (Liverpool): Fibrinous Rhinitis. Owing to pressure of time this paper was handed in to the Secretary.

A vote of thanks to the President and Secretaries completed the business of the Section.

MEDICINE IN RELATION TO LIFE ASSURANCE.

FRIDAY, JULY 29TH.

A paper was read by Mr. J. M. M'CANDLISH, late President of the Faculty of Actuaries in Scotland, upon

The Medical Advisers of Life Assurance Offices: Some of their Duties and Difficulties.

Mr. M'Candlish began by referring to the time when life insurance was conducted without medical examination and without reference to age. Life insurance was founded upon the principle that longevity in the individual is uncertain, in the mass certain, so that the loss entailed in the early death of individuals can be spread over a class, those surviving paying for those dying early. But amongst a group of persons taken haphazard even of the same age some individuals are almost certain to die before the rest and medical examination is the chief means of excluding these and so obtaining a group of cases which might be equitably placed in one class. The duty of the medical officer was not to cure disease, but to detect those diseases and conditions which would be likely to shorten life. Mere ill-health was often of no consequence in life assurance. In the case of annuitants it was found that self-selection acted in favour of the annuitant and probably also it would in the case of life assurance if not corrected by medical and other office selection. Persons were sometimes tempted for monetary reasons to conceal defects in their constitution leading to early death to detect which was often very difficult and sometimes impossible, and here the chief means of detection was the medical examination. Allusion was made to the great social value attached to the subjects of this section.

The PRESIDENT (Dr. MUIRHEAD) said medical examiners sometimes manufactured difficulties for themselves by the abrupt way in which they asked questions. The applicant's trepidation was thus increased and he was apt to answer wildly and even inaccurately. A just estimation of extras for under-average lives was dependent upon the highest faculty of medicine, prognosis, and could only be acquired by long experience and study. It was gratifying to find that the extras, although fixed empirically, had up to now on the whole met the extra risk. Sometimes, however, they had been too high. The actuaries could settle the question equitably by reference to the records of their offices.

Dr. SOMERVILLE, speaking as an examiner, regretted that the reason for deviating from their advice by the chief medical officer was not communicated to the examiners, who were thus left in the dark.

Dr. DAWSON WILLIAMS (London) urged the importance of the medical examiners being acquainted with the working of insurance offices.

Mr. LOW, Actuary and Manager of the Edinburgh Life Office, read a paper on

Extra Rating as a Statistical Problem.

Extra risks must be measured in the same way as ordinary risks by comparing lives at risks with deaths. Allusion was made to the investigations by this method made by Mr. Manly and Dr. Glover Lyon into the extra mortality amongst insurers giving a family history of consumption. From these results it would appear that there was an extra risk more marked in the case where parents had died from consumption than where brothers and sisters had died from that disease. But the paucity of numbers involved in the investigation prevented the results from being accepted as final. The advisability of combined investigation undertaken by all the offices was urged. Mr. Low referred to an investigation made by the statistical methods in the mortality of obese insurers which proved that a considerable extra obtained after five years' insurance chiefly observable between the ages of fifty and sixty, also to that of some Scotch offices on the high mortality amongst liquor-sellers. Their actual deaths exceeded the expected by 83 per cent., 430 against 235. In conclusion, Mr. Low advocated a joint inquiry by actuaries and medical officers into this and kindred questions by means of the records of the life offices. He pointed out, however, that the inquiry now in course of completion into the general experience of the offices stood in the way of such an inquiry for the moment.

The PRESIDENT insisted upon the necessity of attention to individual cases as well as to average, instancing the unfairness that would ensue if all cardiac cases were treated alike.

Dr. GLOVER LYON (London) pointed out a similar injustice involved in putting in the same class all cases, robust and delicate, giving a family history of consumption. He looked forward to a complete inquiry into these points by actuaries and medical officers, and suggested a joint action between American and British offices to meet the expense involved.

Dr. SPRAGUE (actuary) said that in an inquiry not yet published they had found that, amongst 1000 policies whereon an extra had been charged for consumptive family history, the extra charge was about twice as much as it should be.

Dr. RITCHIE (Vice-President) referred to the importance of sometimes considering individual cases on their own merits.

Mr. JAMES MEIKLE (actuary of the Scottish Provident Institution) read a paper upon

Gout as a Factor in Life Assurance.

He gave the mortality experienced amongst 525 cases which had been rated up for gout. There had been 184 deaths amongst these against 111 expected deaths. The mortality amongst gouty publicans was shown to be very high. The

Digitized by Google

extra rates charged had covered only about half the real extra risk.

The PRESIDENT urged the necessity of offices combining to make a uniform extra rate for gout.

Dr. SPRAGUE (actuary) advocated independent action in the matter, remarking that in the long run it would be better not to interfere with the action of offices willing to take unfair risks.

Dr. BALFOUR GRAHAM (Leven) thought the extra risk due to gout had been reduced of late years on account of the discovery of medicinal solvents of the gouty products.

Mr. CHATHAM pointed out the fallacy of rating up endowment policies in the same way as all life policies.

Mr. LOW raised the question as to the value of the figures, relating as they did to old experience; he thought the condition then designated gout might be different from what is now understood by gout.

General Report.

This first meeting in connexion with the Association on the subject of Medicine in relation to Life Assurance was, on the whole, exceedingly successful. This was due largely to the fact that the meetings took place at a centre of life assurance. It is the first occasion on which actuaries have met medical officers in debate by formal invitation and the experiment has proved very satisfactory. The attendance was good at all the meetings, though slow to collect on the first day; during the last two days exceptionally so. The papers were all short, giving ample time for discussion. There was a total absence in the papers and discussion of tedious references to medical points of common knowledge sometimes introduced into such debates; all that was said had a direct bearing on life assurance. The figures submitted were object lessons of statistical science. The conference arranged between the Section of Laryngology and Otology and the above Section by Dr. McBride, in reference to the question of middle ear disease, was a happy thought and proved most successful and instructive. The only flaw in the arrangements—and this was a serious one—was that the meetings took place at the same time as those of Medicine and Surgery. Several members expressed their regret at not being able to be present as they were obliged to be at other sections. Life assurance is not in the ordinary sense a specialty but a special application of medicine carried out by general physicians and surgeons, and meetings to discuss the subject should be arranged so as not to clash with the meetings on general subjects. This might be done by holding the meetings in the afternoon, the other sections being held in the morning. It is scarcely likely that when the Association meets at places not the headquarters of life assurance this section will hold so important a position as in the present instance, nor could a like attendance of actuaries be obtainable. One or two papers, therefore, read in the afternoon on questions of special importance would probably meet the circumstances, if, indeed, it would not be better to omit this subject from the programme except when the meetings are at insurance centres. The predominant note through all the meetings was a desire to get more accurate knowledge of the value of aberrations from the normal by means of a joint inquiry by medical officers and actuaries through the records of life offices.

TROPICAL DISEASES.

FRIDAY, JULY 29TH.

Dr. ANDREW DAVIDSON, LL.D. (Edinburgh), Vice-President, in the chair.

The attendance at this section was very gratifying to the organisers, for up to the very end of the meeting, at 1.30 P.M., on Friday a large number still took an active part in the proceedings. The whole meeting on July 29th was given up to a discussion on Plague.

Dr. W. J. SIMPSON, late medical officer of health of Calcutta, read a paper on

Plague in India.

Dr. Simpson paid a graceful tribute to the excellent work and the heroism displayed in India by medical men, nurses, civil and military officers, missionaries, and native assistants. In India plague was not an endemic disease but an exotic with long intervals of mostly over one hundred years. In 542 A.D. accounts of plague were met with in Indian annals. Some 800 years ago a Hindu writer gave instructions to his fellow-countrymen as to what steps to take in the event of an outbreak of plague and laid stress upon the point that whenever a mortality amongst rats was observed they were to leave the locality. The rat infection was therefore very old as even in Biblical history we found the same animals or rather mice named as sources of infection. In remarkable confirmation of the behaviour of plague in Hong-Kong was the evidence given by Fryer, who stated that the great city of Surat in India was visited by plague in 1684 and that the disease continued for six years. Hong-Kong was now in the fourth year of its infection and there seemed no certainty that the visitation was over. Dr. Simpson was of opinion that the Levantine plague, although allied to the Indo-China plague, was a species that was dying out and different in the acuteness of its powers of infection and destruction from the deadly disease now raging in India and China. He was of opinion that the pandemic form in India might invade countries where the more attenuated form of the disease now existed, and that as plague was a slow traveller it behoved Western Asia and Eastern Europe to keep a careful watch on the spread of the disease. Dr. Simpson discussed the prevalence of fever with glandular enlargements which occurred in the Shropshire regiment, which went from Hong-Kong to Calcutta, after being engaged in cleansing duties in Hong-Kong during the 1894 epidemic there. In January, 1895, the regiment went to Calcutta and this disease was first diagnosed as syphilis, then as malarial fever with bubo, and finally the cause was declared to be unknown. In June, 1896, one of the medical officers to the regiment was attacked with fever and the glands of the neck, axilla, and groin were all enlarged. A goodly number of similar cases were met with in the town; moreover, the rats became sick and the grain stores swarmed with diseased and dead rats. In spite of opposite evidence it was well-nigh certain that plague in a sporadic form had been in Calcutta since 1895 or 1896. Even in the spring of 1898, when plague was in evidence, it was held by some that it was "only malarial fever accompanied by buboes." Dr. Simpson advocated a proper sanitary service for India and gave in detail the essentials of such a service. He continued: "I divide the medical part of a sanitary service into three branches—(1) the administrative, (2) the investigative, and (3) the scientific—which should be in close connexion with one another and in large towns should form parts of one large department. Broadly, in England the administrative is represented by the local health officers and their subordinates, the investigative by the medical inspectors of the Local Government Board, and the scientific by the laboratory researches made into the causes of disease in connexion with special investigations of either the medical inspector or local health officer. The Government of India has always been imbued with the great importance of establishing laboratories in India, but the state of finances has invariably blocked the way. This difficulty, however, disappeared in a most charming and unexpected manner in 1897, when a number of the Princes in India expressed their desire to commemorate the sixtieth year of Her Gracious Majesty's reign by establishing a Health Institute for India, which should have M. Haffkine as its first director. The spontaneity of the offer and the generosity with which it was made were enhanced by the peculiar appropriateness of this Royal memorial to our beloved Empress Queen, whose reign has been so distinguished for the advances made in scientific and preventive medicine. The Princes were anxious that the site should be chosen and the foundation of the Health Institute laid on the day of the Jubilee. Owing to delays over which possibly the Government of India had not full control, in consequence of its plague and famine work, the auspicious day was allowed to pass and no foundation-stone was laid. Everyone acquainted with India will know the importance of an auspicious day. It is the symbol of success and good fortune."

Professor W. M. HAFFKINE, C.I.E., and Surgeon-Major BANNERMAN, I.M.S., communicated a paper on

The Testing of Haffkine's Plague Prophylactic in Plague-stricken Communities in India,

which was read by the HONORARY SECRETARY. A series of experiments upon animals was recorded and the immunity conveyed and the powers of recovery of protected persons by inoculation with plague serum were stated. It

Digitized by Google

would appear from undeniable testimony that the protection afforded was most pronounced and that the possibility of recovery of inoculated persons when attacked was highly satisfactory. As examples of protection the following statements were given: 1. Half the inmates of the Byculla House of Correction were inoculated with Haffkine's serum on Jan. 30th, 1897. From this date the inoculated and uninoculated lived together under exactly similar circumstances during the time plague prevailed. Of 173 unprotected persons 12 were attacked by plague and 6 died; and of 148 protected persons 2 were attacked and none died. 2. During 1897 8200 persons were inoculated in Bombay, of whom 18 (all natives) were attacked and only 2 died, and these two developed plague symptoms within twenty-four hours after inoculation. 3. In Lanowlie, a small hill station near Poona, with a population under 2000, a recrudescence of plague occurred. The officers of the Research Laboratory took charge of two wards of the town most severely attacked and made a house-to-house visitation, carefully noting the effects of previous inoculation. Of 323 protected inhabitants 14 were attacked and 7 died; whilst of 377 unprotected persons 78 were attacked and 58 died—a reduction in mortality by inoculation of 85·7 per cent. 4. Of a section of the Mussulman community of Bombay 5184 were inoculated and 8146 remained unprotected. Amongst the former 7 deaths and amongst the latter (the unprotected) 177 deaths occurred from all causes. Altogether inoculation lessened the mortality by 86 per cent.—a result which was sufficient to establish inoculation as a preventive and remedial agent in plague of high value.

Brigade-Surgeon-Lieutenant-Colonel DIMMOCK, I.M.S., gave a brief outline of

The Measures Adopted for Dispelling Plague in Bombay.

It would appear that the city was carefully watched, inspected and disinfected by well-organised bands of workers from almost the very commencement of the epidemic, and that unceasing endeavours were made to induce the native population to accede to the requirements of sanitation.

An abstract of Surgeon-Captain L. F. CHILDE'S report to the Plague Research Committee in Bombay on the

Pathology of Plague

was read by Brigade-Surgeon-Lieutenant-Colonel ARNOTT. Plague, according to Surgeon-Captain Childe, is met with in three varieties. First, the bubonic form. In this variety the main glandular lesion was met with at the seat of the primary bubo and but slight signs of disease were found in other glands. Associated with this engorgements and petechiæ or hæmorrhages were found in nearly all viscera. Second, the septicæmic form. Glandular enlargement in this phase of the disease was general in all parts except in the mesenteric glands. Here evidences of change were less distinct and the necropsies showed that the plague bacillus had not reached the stomach or intestines by the food. Third, the pneumonic form of plague. Whilst the lymphatic glands and other organs were scarcely affected the lungs were engorged with pneumonic patches here and there, or occasionally half the lower lung was found in this state. The bronchial glands were either swollen or œdematous or quite normal.

Surgeon-Major BAKER, I.M.S., referred to the great danger to which workers at house-cleaning in plague were subjected when infected materials were handled or moved by them before disinfectants were applied.

Mr. CANTLIE (London) referred to the excellent work done by Yersin, but wished to discredit the notion that Yersin's name should be associated with Kitasato's in the discovery of the plague bacillus. Kitasato was demonstrating plague bacilli a week before Yersin had his preparations ready. Mr. Cantlie stated that he believed India was only commencing her plague troubles and that the urgency for a sanitary service for India as suggested by Dr. Simpson was imperative.

After the business of the meeting was over Dr. ANDREW DAVIDSON, the chairman, proposed that the section should send a message of congratulation to Surgeon-Major Ronald Ross at Calcutta upon the brilliant work he has done in connexion with the extra-corporeal life of the plasmodium malariæ and that a vote of thanks be accorded to Dr. Patrick Manson for his exposition of and share in Surgeon-Major Ross's work.

The proposition was unanimously carried, as was also a vote of thanks to the honorary secretaries.

PHYSIOLOGY.

WEDNESDAY, JULY 27TH.

Professor WILLIAM RUTHERFORD (Edinburgh), the President of the Section, delivered an address on

Tone Sensation with Reference to the Function of the Cochlea.

This address is published in another part of our present issue.

Dr. AUGUSTUS D. WALLER (London) read a paper on

The Action of Anæsthetics on Vegetable and Animal Protoplasm.

This was an extension of previous work on the action of anæsthetic gases on living matter in which nerve and muscle were used as representative examples. In the present research other protoplasmic tissues, such as spinal cord and retina, and vegetable protoplasm in the form of cells of vallisneria, *Elodea Canadensis* (the Canadian duckweed), and nitella were investigated. Dr. Waller then gave a brief explanation of his method of experiment by a series of lantern slides, showing the arrangement of the nerve upon the stimulating or "questioning" electrodes and the electrodes connected with the galvanometer or "answering" electrodes. He then described an apparatus by which the effects of a stream of an anæsthetic gas could be studied on a vegetable cell (e.g., of elodea) and a frog's nerve simultaneously, the stream of gas passing through a moist cell in which the vegetable cell was examined by a microscope and then through a moist chamber in which the frog's nerve was arranged in the usual way. The effect on the vegetable cell was studied by watching the rotation movements of the protoplasm and counting the number of chlorophyll bodies which passed a given spot per minute; the effect on the nerve was studied in the usual way by the galvanometric response. The results were as follows: nitrous oxide had little or no action on nerve, and the same result was obtained with vegetable protoplasm. Carbon dioxide caused a diminution of the electromobility of the nerve and an arrest in the movements of the plant protoplasm, followed in each case by a return to and beyond the normal as the effect passed off. Ether caused a diminution or arrest of these functions followed by a return to the normal both in the case of the nerve and of the plant. Chloroform caused complete and permanent abolition in both cases. Dr. Waller had also studied the effect of anæsthetics on the electrotonic currents obtained in a long cell of nitella—e.g., carbon dioxide caused a temporary abolition of these currents which returned as the carbon dioxide passed off. He had also studied the effect of anæsthetics on the retinal currents obtained by illuminating the eyeball of a frog with standard amounts of light at regular intervals and found the same difference between the action of ether and chloroform as he had previously found for nerve. In confirmation of these results he had also investigated the effect of ether and chloroform on the reflex excitability of the frog's spinal cord. A slight dose of strychnine was given and the frog arranged in a bell jar and a slight touch applied to its hind limb at a definite rate, say once a minute, yielding a reflex jerk. He found that ether abolished this reflex response, but only temporarily; chloroform, on the other hand, abolished it completely and permanently. It was of interest to note that these effects occurred with weaker strength of ether and chloroform than was the case with nerve or the heart. On the whole, however, nerve was by far the best living tissue to use in these investigations.—In the discussion which followed Professor WAYMOUTH REID objected that since the frog was suspended in a bell jar—the air of which was impregnated with the vapour—a possible fallacy existed in that the results might have been primarily due to the action of the anæsthetic on the endings of the nerves in the skin.

Dr. CORSAR STURROCK (Edinburgh) then read a paper on the

Selective Power of Tissues,

especially as illustrated in the mammary gland, in which he first briefly discussed the process of selection in general and then pointed out that no tissue possessed this power in so striking a degree as the mammary gland, since it produced a material, not for the nutrition of its own cells or of the organism of which it is a part, but of an entirely different organism. It selected from the blood a food, milk, resembling in the proportions of its constituents the freely-chosen diet of an adult, from which it, however, differed in the

Digitized by Google

following particulars: (1) the suckling required more proteid and salts than an adult for purposes of building up its tissues, since anabolism was in excess in the growing animal; (2) the suckling required more fat as heat-producing material since it had not developed to such an extent as the adult the muscular source of heat-supply; and (3) the adult required more carbohydrate because he performed more work. A study of the milk of various animals showed that their mammary glands selected the constituents of milk in proportions adapted to the diverse conditions of life under which the animals were placed—e.g., animals which grew rapidly were supplied with milk containing more proteid and salts than the milk of animals which grew slowly. Animals living under different conditions of temperature were provided with milk containing constituents more or less useful for the maintenance of body heat. Animals compelled to early muscular exertion received milk adapted to supply the material for the production of muscular energy. A chemical investigation of the cells of the mammary gland proved the existence in them of a nucleo-proteid which was of a highly complex constitution, containing a nuclein, a carbohydrate, and a proteid radicle. It might be the antecedent of caseinogen and of lactose. It contained a true nuclein, whereas caseinogen was a pseudo-nucleo-albumin. The nuclein bases which it contained were not excreted, but seemed to remain in the gland, probably in the nuclei of the cells as active agents in the formation of more mother-substance. Phosphocarnic acid—described by Siegfried as a constant constituent of milk—was present in the mammary gland in considerable quantities. It could also be split off from caseinogen by the action of rennet. It was more abundantly present in human than in cow's milk.—In discussing Dr. Sturrock's paper Professor WAYMOUTH REID remarked that an excellent example of the relation existing between the chemical nature of milk and the growth of the young was found in the case of "pigeon's milk." While the young birds were fed by their parents on this substance (a secretion from the crop containing nucleo-albumin, fats and salts) they grew at about ten times the rate which obtained during the subsequent period of grain-feeding.

THURSDAY, JULY 28TH.

Professor WAYMOUTH REID (Dundee) opened a discussion on

Intestinal Absorption.

The object of the discussion was to determine to what extent experimental evidence justifies the view that the absorption of aliments could be explained on physical grounds. The two main views held by physiologists on this subject were—(1) that osmosis and filtration were sufficient in themselves to account for the absorption of dissolved food substances; and (2) that the cells covering the villi took an active though unknown part which may be referred to as "cell action." To speak of cell action does not necessarily imply a belief in vitalistic action. He then illustrated by diagrams the effect of the partial osmotic pressures of the substances dissolved in the gut and in the blood and of the hydrostatic pressure on either side of the membrane on the process of absorption, from which it could be inferred that in the case of a substance to which the gut wall was permeable being in solution in the gut a suitable mechanism for absorption on simple physical lines existed. If the special case be considered in which the fluid in the gut was identical with that in the blood-vessels—i.e., when the serum of an animal was introduced into its own intestine—osmotic phenomena need not be taken into consideration and the only physical factor to consider was the difference of hydrostatic pressure. Professor Reid then gave a brief record of the results obtained by other observers by this method and then referred to his own experiments, in which, after the introduction of a measured quantity of its own serum into a loop of a dog's intestine and withdrawal after a given time, it was found that absorption occurred in spite of the fact that the hydrostatic pressure in the gut was well below that in the veins of the loop of intestine. This could not be explained by *ad*sorption or imbibition, but pointed to "cell action." This is confirmed by the results of removal of the epithelium of the gut. This was done more or less completely by various methods such as by producing a temporary anæmia of the gut-wall by clamping its vessels before the experiment or by the use of weak solutions of such drugs as sodic fluoride or osmic acid. In these cases absorption was much lessened and the absorption of water sometimes completely abolished in the case of sodium fluoride experiments. He therefore concluded that the epithelial cells are agents in the process of absorption of solutions from the gut, though not of necessity the sole agents. Certain experiments with peptone and glucose were then recorded which he regarded as suggestive of epithelial action in the absorption of these substances, though not conclusive—e.g., whereas glucose was more diffusible than peptone it was actually absorbed rather more slowly. Professor Reid had found in the serum experiments that the absorption of organic solids was much slower than that of the water while the salts were taken faster. He had found no evidence of nerves exerting an influence on the activity of the epithelial cells comparable to that of secretory nerves on gland cells.

Dr. NOEL PATON (Edinburgh) asked whether Professor Reid had considered or experimented upon the possibility of the rate of absorption being different in different parts of the intestine, to which Professor REID replied that he was investigating this point, the results of other observers being discordant.

Dr. DAWSON TURNER (Edinburgh) then demonstrated an experiment by Mr. Shelford Bidwell on the production of complementary colour sensations. The apparatus consisted of a disc, of which one sector was blackened, another was white, while the third sector was cut away. This open sector was arranged so as to succeed the blackened portion when the disc was rotated. A coloured object, strongly illuminated, was then looked at through the open sector of the revolving disc; if a proper speed of rotation were maintained no trace of the original colour was seen, but only the complementary colours, thus showing that a very short stimulation of the retina (rendered hyperæsthetic by the black sector) was sufficient to produce a strong negative after-image.

Professor G. N. STEWART read two papers: (1) On the Relation between Molecular Concentration (as Determined by the Lowering of the Freezing-point) and the Electrical Conductivity of certain Animal Liquids, with Special Reference to Blood; and (2) On the Changes which take place in the Electrical Conductivity and Molecular Concentration of certain Animal Liquids and Artificial Nutrient Media with the Growth in them of Putrefactive Pathogenic Micro-organisms. The red corpuscles of blood were practically non-conductors, but if blood be "laked" by distilled water electrolytes were set free and its conductivity was increased. However, if it was allowed to "lake" spontaneously its conductivity was unaltered. In that case it was probable that the electrolytes remained in the "shadows" of the red blood corpuscles, from which they might be set free by the addition of distilled water. If blood was allowed to putrefy its conductivity at first increased, but after a time became constant. A similar result was obtained with serum. This was due to the fact that the proteids which were not electrolytes had been broken down into simple bodies which were electrolytes, as shown by the progressive depression of the freezing point of the solution. Similar experiments were carried out with nutrient fluids such as peptone solutions in which various micro-organisms were grown with interesting results, the resistance getting less as the growth increased, and the freezing point being lowered owing to the breaking up of the peptone into simpler substances.

Professor MACALLUM read a paper on

Some Points in the Micro-Chemistry of Nerve Cells.

The object of the research was to elucidate the origin and nature of Nissl's granules. Their arrangement in the normal nerve cells of the anterior horn of the spinal cord of the dog was first described. These were often zones free from granules, especially round the nucleus and at the periphery of the cytoplasm. Since it had been suggested that these granules were precipitation products their genesis was studied in pig embryos, and diagrams were shown illustrating the cells at different stages, at first containing no granules and a nucleus very rich in chromatin; later a cap of substance taking the stain was found outside the nucleus, the nucleus containing less chromatin; later still this staining material increased in quantity and became granular. These experiments carried out by Mr. Scott suggested that Nissl's granules were probably derived from the nucleus, and this view was supported by their micro-chemical reactions, since they did not digest with pepsin-hydrocloric acid but they dissolved very

Digitized by Google

slowly in weak alkalies and were therefore probably nucleo-proteid in constitution. They were rich in iron, like the chromatin of nuclei, and contained phosphorus as shown by Professor Macallum's modification of Lilienfeld and Monti's micro-chemical reaction, in which phenylhydrazine was used to fix the colour.—In answer to Dr. MILROY, Professor MACALLUM stated that these granules gave the phosphorus reaction after treatment with pepsin-hydrochloric acid.

Professor W. H. THOMPSON (Belfast) read a paper on

The Influence of Peptone and its Precursors on the Work of the Kidney,

in which he gave a brief account of the physiological effects of albumose and peptone on the vaso-motor system and showed that none of them produced much effect on the vaso-motor apparatus of the kidney as compared with that on the splanchnic vaso-motor system generally. Tracings were shown of the effect of injection of peptone on kidney volume and general blood-pressure. He then described the influence of albumoses and peptone on the flow of urine as collected by cannulæ in the ureters. There was a great increase in the flow of urine in the second hour after the injection reaching a maximum in the third and becoming less in the fourth and fifth. By a study of the total nitrogen and the nitrogen excreted as urea, and allowing for the extractive nitrogen, it was found that a considerable amount (from 28 to 57 per cent.) of the injected albumose or peptone appeared in the urine, and this within the first 45 to 50 minutes.

Dr. FRASER HARRIS (Edinburgh) read a paper on

The Physico-chemical State of Caseinogen,

in which he gave a summary of the views held as to the relation of the caseinogen to the fat. He then described the relative amount of fat and caseinogen in the globules and the particles of milk, in cream, in centrifugalised milk, &c., and showed that caseinogen did not exist in solution in the milk plasma and that Ringer's solution of caseinogen was not a true solution. Caseinogen always occurred in company with the fat, though neither the "solution" nor the "envelope" theories would explain the amount of caseinogen in cream. The globules of milk were richer in fat, the particles richer in caseinogen. Caseinogen was to be regarded as part of a complex oleo-nucleo-proteid formed by the mammary gland cells.—Professor WAYMOUTH REID pointed out that proteids did not form true solutions and referred to the mechanical precipitation of egg albumin by Ramsden.

FRIDAY, JULY 29TH.

Dr. NOEL PATON (Edinburgh) read a paper on

Protoplasm and Zymin Action,

in which he recorded experiments with post-mortem livers and alcohol-hardened livers respectively which tended to show that the change of glycogen into sugar in the liver post mortem was due to katabolic changes in the liver protoplasm rather than to the action of a zymin such as hæmodiastase.

Dr. NOEL PATON also exhibited for Mr. MAHALANOBIS an Electrical Key for Physiological Experiments which could be used as a reverser or for sending currents alternately in different directions or to eliminate the make-or-break shocks.

Dr. W. BAIN (Harrogate) read a paper on

An Experimental Contribution to the Study of the Mechanism of Bile Secretion.

In this paper he first gave an outline of previous work on the influence of the nervous system on the flow of bile and then recorded experiments in which he had operated on dogs by Pawlow's method and then tied a graduated tube into the bile-duct. On stimulation of the vagi no effect on the bile flow was observed. With regard to the influence of cholagogues he had experimented by injecting the substance investigated into the external jugular vein and therefore regarded the effects he obtained as due to a direct action on the liver cells. He obtained a distinct increase in the flow with a solution of Plattner's crystals. 50 c.c. of strong sulphur water (Harrogate) produced a distinct and sustained increase. The action of the sulphur water was probably due to the sulphide of soda and barium chloride which it contained.

Dr. W. BAIN brought forward a second communication on

The Secretion of Bile in Man

in which he briefly referred to some conclusions to which he had arrived from the investigation of a case of biliary fistula. He had found no relation between the weight of an individual and the amount of bile secreted after a comparison of his own with other recorded cases. Diet exerted an influence on the flow, largely depending on the amount and nature of the food taken; the amount of liquid taken probably also exerted an influence. Exercise caused an increased bile flow provided perspiration was not too great at the same time. It was important in considering the bile flow to consider also the amount of bile solids. Bile and bile salts were almost universally admitted to be cholagogues.

Professor RUTHERFORD read a paper on

The Secretion of Bile in the Human Subject.

It was the result of a series of observations made on a patient (the subject of cancer) with a biliary fistula. The bile was collected every hour and the daily flow was found to be very regular. A chart showing the daily secretion of bile was shown; from this it was seen that after breakfast and dinner there was a rise in bile secretion which took place within an hour after the taking of food and was long maintained. A few observations were made on the influence of drugs. Morphia had no effect, as Professor Rutherford had previously observed in the dog. Salicylate of soda caused an increase, as did also salicin in one observation.

Dr. PATON showed for Dr. MONCKTON COPEMAN continuous tracings of the Daily Flow of Bile recorded by an apparatus devised for that purpose. The tracings were fairly uniform and presented very little variation. Dr. Paton himself regarded food as exerting very little influence on the flow of bile and suggested that the morning rise might be due to muscular activity. With regard to the action of drugs he regarded it as very difficult to determine whether any effect obtained was due to a direct action on liver cells or not.

Professor WAYMOUTH REID, quoted the experiments of Dastre on the dog, in which he found no direct effect from the ingestion of food but an increase from six to eight hours afterwards, which he suggested was due to the absorbed products acting on the liver or its nervous mechanism.

Mr. MAYO ROBSON had made observations on two cases of biliary fistula in healthy subjects and had found very little effect on the bile flow from the administration of drugs. He had obtained some slight increase with soda, soda-water, and iridin.

Professor G. N. STEWART also spoke. Dr. W. BAIN and Professor RUTHERFORD replied.

Dr. CARLIER (Edinburgh) read a paper on

Changes which occur in some Cells in the Mucous Membrane of the Newt's Stomach during Digestion.

The specimens were fixed by a corrosive method and double-stained. In newts which had fasted ten days the cells of the oxyntic glands of the stomach were seen to be large, with numerous large zymogen granules, which were not arranged in zones as in the pancreas. The nuclei were large and contained numbers of lanthanin granules. The changes at various intervals after ingestion of food were then described. 20 hours after food the cells appeared wasted and shrunken, the zymogen granules were few and small, and the nucleus was small and shrivelled, while the nucleoli had increased in size. 68 hours after food the zymogen granules were again large and present in greater numbers, the nucleus was clouded, the nucleoli were large and might be extruded from the nucleus. 144 hours after food the cells had returned to their normal condition. The changes in the cells were then described at shorter intervals after the taking of food, from which it was concluded that as soon as food was swallowed secretion began in the glands nearest the œsophageal end of the stomach and swept as a wave over the whole of the glands, reaching those near the pylorus last. This activity reached a maximum in from three to four hours and was then followed by a second period of rest and recuperation with the formation of fresh zymogen. Dr. Carlier then discussed the part played by the nucleus in the process and inclined to the view that the nucleus manufactured a prozymogen, which was subsequently converted into the zymogen granules. Professor MACALLUM corroborated Dr. Carlier's observations on prozymogens and stated that these bodies were rich in iron and phosphorus and were derived from the chromatin of the nucleus.

Dr. T. H. MILROY (Edinburgh) and Dr. J. MALCOLM (Edinburgh) brought forward a paper on

Metabolism of Nuclein under Physiological and Pathological Conditions.

The paper first gave a summary of the cleavage products of

Digitized by Google

nucleo-proteids outside the body and then the results of gastric and pancreatic digestions of the nucleins. Experiments were then recorded describing the actions of the absorbed products of nuclein digestion upon the formation and destruction of leucocytes. The nature of the decomposition products of the nucleins which appeared in the urine and their significance as a measure of nuclear breaking down were then discussed, especial reference being made to the importance of a disturbance of the ratio of nitrogen to phosphoric acid excretion (N : P_2O_5) in the urine, and the care that was necessary in drawing conclusions as to nuclear breaking down from the amount of alloxuric bases in the urine. They then shortly referred to the conditions existing in medullary leucocythæmia with special reference to the relationship existing between the number of leucocytes in the blood and the decomposition products of nucleins appearing in the urine.

Dr. CARLIER read a short paper for Dr. LOVELL GULLAND (Edinburgh) on

The Presence of Nerves on Intracranial Blood-vessels.

Obersteiner described their existence in an old gold-stained preparation. Dr. Gulland at first failed to find them, but recently, using Cox's modification of Golgi's method, had demonstrated an open network on the blood-vessels of the pia mater.—Professor G. N. STEWART stated that he had seen preparations by Professor Huber demonstrating their existence.

Dr. T. H. MILROY read a paper on

The Chemical Changes in Pelagic Ova during Maturation.

The specific gravity of the unripe pelagic ova was much greater than that of the mature ova, which had a specific gravity only slightly greater than that of sea-water. This was due to the absorption of water as the process of maturation proceeded; at the same time there was an increase in the albumin, the salts, and an organic phosphorus-holding body closely allied to ova vitellin. There is no synthesis of inorganic phosphorus compounds to organic phosphorus compounds in these ova.

Dr. NOEL PATON (Edinburgh) had found such a synthesis in salmon ova.

The meeting of the section concluded with a vote of thanks to Professor Rutherford.

THE PATHOLOGICAL MUSEUM.

SECOND NOTICE.[1]

IN our former notice we referred to the excellence of the educational and surgical exhibits. We now propose to mention some of the exhibits illustrating clinical medicine and pathology, which are quite on a par with the others.

CEREBRAL TUMOURS.

The Museum at the Edinburgh meeting would be remembered if only for the unique collection of intracranial tumours which it contained. This was so complete, and the subject is, so to speak, so much the order of the day, that we propose to notice the specimens in some detail, taking them for convenience of reference in order of localisation, mentioning quite briefly the symptoms which were associated during life. It will be remembered that the symptoms are of two kinds, those which occur in all intracranial tumours (headache, giddiness, &c.) and those varying with the locality affected. It is the latter with which we are now concerned. No. 426 is a large Sarcoma springing from the dura mater and causing atrophy and destruction of the right motor area. The case was that of a female, aged twenty years; there was absolutely *no paralysis;* there were only optic neuritis and other general symptoms of cerebral tumour; the patient died with convulsions. No. 427 is a Glio-sarcoma causing destruction of the left motor area without producing any notable paralysis until four days before death during an epileptiform seizure. No. 430 is a large Glio-sarcoma occupying the right centrum ovale, specially involving the internal capsule and optic thalamus. The patient was a male, aged forty-six years; there were left hemiplegia and hemianæsthesia, afterwards right hemiplegia, also conjugate deviation of the head and eyes towards the affected side; coma and death occurred after a history of only four months' duration. No. 436 is a large Aneurysm of the right posterior cerebral artery projecting into the lateral and third ventricles with softening of the brain around. There had been partial left hemiplegia, defective articulation and deglutition, progressive amentia and drowsiness. Nos. 428 and 429 are two specimens of Glio-sarcoma involving and destroying the temporo-sphenoidal and other lobes, unattended in either case by word-deafness, although this centre was involved, or other localising symptoms. No. 432 is a case of Melanotic Sarcoma scattered throughout the Brain Tissue, the largest deposit occupying the left occipital lobe (cuneus). The patient suffered from paroxysms of flashes of light in the right eye. The history was interesting as showing that apparently innocent pigmented moles may become malignant, for the patient had a pigmented mole on the right shoulder which remained of the size of a three-penny-piece until it was injured at the age of ten years, when it started to grow. When the patient was twenty-one years it had enlarged to the size of half-a-crown and was removed by scraping, but it recurred and was again excised at the age of twenty-five years. The following year she manifested symptoms of intra-cranial tumour and she died at the age of twenty-six years. Nos. 434 and 435 are two specimens of Tumour of the Pituitary Body. The tumours were as big as a small and large plum respectively; one was solid throughout, the other appeared cystic in parts. No symptoms of acromegaly were present in either patient during life. The first was a girl, aged twenty-one years, and the only lesion found after death was a great enlargement of the pituitary body. The earlier symptoms of the illness, which lasted five years, were gradually increasing blindness, occasional headaches, and vomiting; the later symptoms consisted of atrophy of the optic discs, increasing headache (occipital), vomiting, and giddiness; the termination was by coma. Nos. 439 and 433 are two cases of Tumour of the Cerebellum without any paralysis or other localising symptoms during life. One was a female, aged sixty-four years, in whom there existed a sarcomatous tumour of the dura mater of the size of a plum, deeply indenting the left lateral lobe of the cerebellum. No symptoms of *any kind* referable to cerebellar tumour were observed during life except that she died from convulsions. She had mitral disease and dropsy and seven weeks before death had "a stroke" followed by right hemiplegia due to a small hæmorrhage in the left lenticular nucleus. The other case was that of a woman, aged sixty-one years, in whom there existed a cancerous nodule in the right lobe of the cerebellum and a smaller one in the left lenticular nucleus secondary to cancer of the breast. There had been no paralysis during life or other localising symptoms; only optic neuritis, headache, and the other general symptoms. No. 439A showed 4 Scrofulous Tumours in the Cerebellum, 3 in the left and 1 in the right lateral lobes; they occurred in a male patient aged seventeen years. There was very slight weakness of the right side, but no definite paralysis, no alteration of gait, or other localising symptoms; there were double optic neuritis, headache, giddiness, &c. He died after a six-months' illness. No. 437 represented a Perforated Sarcoma of the Skull in a boy, aged four years, in whom a lump had been noticed over the vertex only twelve weeks before death. The foregoing were all exhibited by Dr. Byrom Bramwell. Cerebral Tumours were also exhibited by Dr. Alexander Bruce, Dr. George Murray, Dr. W. G. Richardson, Dr. David Drummond, and others. It seemed a pity that no clinical records accompanied these specimens with the exception of the last-named exhibit, since more than half of the interest lies in the associated symptoms during life.

The general conclusions to be drawn from the preceding are most valuable: 1. It is clear that tumours may occupy the motor and other regions to which well-defined symptoms have been assigned without producing those symptoms. This is specially exemplified by the two specimens under No. 439, for in one a hæmorrhage occupying the left lenticular nucleus produced right hemiplegia, but a sarcoma in the same position, although apparently destroying the nucleus, was not so attended. In slowly growing tumours it can be readily understood that the adaptability of brain matter prevents its destruction; but in rapidly growing lesions such as many of these were it can only be presumed that the remarkable power of "substitution of centres" which the brain possesses came into operation. 2. Nevertheless, from an examination of these specimens it may be concluded that cerebral tumour rarely exists even in the frontal region without producing the general symptoms—headache, giddiness, vomiting, convulsions, and optic

[1] The First Notice was published in THE LANCET of Aug. 6th, 1898.

Digitized by Google

neuritis—which have been regarded as significant of intracranial tumours.

It is appropriate that Scotland, which produced an eminent surgeon (Macewen) whose name is associated with cerebral surgery, should furnish such a rich collection of cerebral tumours; and now it is to two Scotch observers that we are indebted for the first really simple system of cranio-topography. It is perhaps strange that Chiene and Stiles's method is not better known. This Museum contained very complete series of specimens and photographs illustrating these observers' investigations and they showed conclusively how complete is the precision of their measurements for ascertaining the exact position in the cranium of any given centre in the brain. Their system is special (1) in depending on bony prominences from which straight lines are drawn, (2) without measuring angles and (3) without measuring in inches, for (with one exception) all the lines are halved to locate a convolution.

DRAWINGS AND PHOTOGRAPHS.

A very beautiful Series of Pictures illustrative of almost the entire range of clinical medicine is to be found in Dr. Byrom Bramwell's original plates (coloured and photographic), from which his "Clinical Atlas" was prepared. They occupied half the entire side wall of the Museum—a space measuring 50 ft. by 10 ft. Among the subjects illustrated are Ichthyosis, Lupus Vulgaris, Lupus Erythematosus (one of the most life-like representations imaginable), Anæsthetic Leprosy, Psoriasis of the Palms, Black Jaundice, Scurvy, Purpura Hæmorrhagica, Cyanosis, Thoracic Aneurysm, Myxœdema, the Clubbed Fingers of Congenital Heart Disease, Chlorosis, Addison's Disease, and the Expression in Various Forms of Mental Disease. In all a perfect type of the disease has been taken and the completeness of the collection is evidenced by two plates illustrating two patients affected with the epidemic skin disease which occurred in London in 1891 and occupied a good deal of professional attention at the time.

A radiograph measuring 30 in. by 18 in., by Dr. John Macintyre (of Glasgow), representing a case of Transposition of the Viscera, makes us hope once more that we may some day be able to detect hypertrophy of the heart and the outlines of other solid viscera by means of the x rays.

DERMATOLOGY.

Among the most notable changes which have taken place in this department of general medicine during recent years is the reclassification of bullous and vesicular eruptions. Formerly everything bullous was called pemphigus, but owing to the researches of Unna, Duhring, and others a new group, named Dermatitis Herpetiformis, has been sorted out of the pemphigus class, which is characterised clinically by the bullæ varying very widely in size and occurring in clusters. The most interesting of a set of pictures exhibited by Dr. Allan Jamieson illustrate the 3 principal varieties in which this disease occurs—viz., (*a*) the Erythematous, (*b*) the Vesicular, and (*c*) the Bullous forms of Dermatitis Herpetiformis. Among the other subjects illustrated by this exhibitor are the following: Lichen Scrofulosorum; Angio-keratoma; a very curious warty, horny, or fungating condition on the arm which the exhibitor has named Paraffin Ichthyosis; Tinea Tonsurans around the anus simulating a mucous tubercle; and a case called Acanthoma of the Leg—an extensive warty or tuberculous thickening suggesting some strumous affection or granuloma fungoides. Dr. Radcliffe Crocker exhibited a remakable series of Ten Drawings showing the various stages (though not taken from the same case) of that rare condition Mycosis Fungoides. The first and most important stage of this disease may often take a form resembling psoriasis or eczema or pityriasis rubra, each of which is here represented. In any case it is purpuraceous and may have a raised scurfy edge. This is followed by the tumour stage, which the exhibitor likens to pityriasis rubra, and finally the stage of ulceration. Mr. Malcolm Morris and Professor McCall Anderson also exhibited sets of Dermatological Sketches and Dr. Norman Walker showed a series of Microscopic Sections in the same subject.

GENERAL PATHOLOGY.

From the Museum of the Hospital for Diseases of Children comes an admirable collection in illustration of Hydrocephalus; Gummatous, Tuberculous, and Rachitic Lesions; and Congenital Heart Disease. Perhaps the most interesting specimens in this series are the gastric ones, which include three stomachs, the seat of congenital hypertrophy of the pyloric and stomach wall, taken from children aged twenty-eight days, forty-eight days, and nine and a half weeks respectively—a rare and interesting condition. Unfortunately the associated symptoms are not mentioned.

Dr. Alexis Thomson (Edinburgh) exhibited Shoulder-joints almost totally disorganised from a case of Locomotor Ataxy, and another from Syringomyelia. It is only of late years that we have learned the last-named association and our readers will recollect a very remarkable case of extensive disorganisation of the shoulder-joints which was regarded by a committee of the Clinical Society as the result of chronic pyæmia, but which was proved post mortem to be due to syringomyelia.

Apparatus for Serum Diagnosis were exhibited by Dr. H. E. Durham and Dr. Robert Muir (Edinburgh). A neat little contrivance for Vidal's Sero-sedimentation Test for Typhoid Fever was exhibited by Dr. D. H. Hutchinson (Edinburgh). The test depends on the fact that if a patient be suffering from enteric fever some of his serum when added to broth containing enteric microbes cause the latter to agglutinate into little bundles and fall into a sediment. The apparatus exhibited is practically two U-tubes cemented together. In one the suspected blood is placed; the other contains some normal serum treated in precisely the same way. Thus we have a control experiment and the test side by side. Some excellent photographs of the experiments (which form the basis of the exhibitor's M.D. thesis) are also shown.

Microscopic sections illustrating the extremely minute microbe of the Pictou Cattle Disease,[2] a disease believed by the exhibitor[3] to resemble a form of cirrhosis of the liver in man, were shown by Professor Adami (Montreal). Dr. Graham Brown showed a series illustrating various forms of Cirrhosis of the Liver in the Human Being.

Dr. Greenfield exhibited a Series of Entire Sections of Organs of Microscopic Thickness. The sections are placed between two plates of glass measuring about 12 in. by 8 in. In this way the observer is enabled to study, either macro- or micro-scopically, pulmonary apoplexy, chronic phthisis in its various stages of deposit, softening, and cavitation, acute miliary tuberculosis, a chronic thickening of the pleura measuring about ¾ in. thick, supposed syphilitic interstitial pneumonia, septic nephritis, infarct of kidney, plastic cast of bronchitis, broncho-pneumonia, and miners' anthracosis.

That rare condition Achondroplasm was illustrated by Dr. Alexander Bruce (Edinburgh), who showed an excellent Plaster Statue. Photographs, skiagrams, and bottled preparations were also shown by Dr. John Thomson and Dr. Harry Rainy. The disease consists of a delayed ossification of the bones and delayed development of the muscles and soft parts. It resembles rickets in some respects and is probably the cause of dwarfism. The most characteristic feature of this disease is the face, by means of which it can be recognised—forehead broad, nose flat or undeveloped, and lips thin. Puberty is delayed and the body, strange to say, may continue to develope up to the age of thirty-five years. The celebrated Tom Thumb and his wife were probably examples of this condition.

THE ANNUAL MUSEUM.

(Continued from page 380.)

III.—SANITARY APPLIANCES, DISINFECTANTS, &c.

Under this heading we may deal with disinfectants, antiseptics, filters, and so forth. A special space was allotted in a small hall adjoining the Drill Hall to what was described as a sanitary department, but this related, with the exception of a working model of the septic tank system of treating sewage at Exeter, to the furniture of hospitals, illustrations of aseptic wards, operating theatres and dental operating accessories rather than to public sanitary matters. With this section we shall deal in Division IV. under the heading of Surgical Instruments and Appliances. The Working Model of the Tank System of Sewerage Treatment, which is shortly to be carried out on a scale applied to the whole city of Exeter, evoked considerable interest. Specimens of sewage before and after treatment were submitted for inspection. Turning to methods for

[2] See the paper by Professor Adami on p. 396 of this issue, as a special supplement to which reproductions of these sections are published.

Digitized by Google

combating organisms rather than encouraging their growth we may appropriately refer to the exhibit of Messrs. J. Defries and Sons (147, Houndsditch), whose representatives demonstrated the many industrial as well as scientific applications of the Pasteur (Chamberland) Filters. There was a Plan of the Waterworks Filter at Darjeeling of which the output is 250,000 gallons per day, and close by was a photograph illustrating the working of the Equifex disinfector as used in Bombay harbour, the temperature attained being 239° F., while a useful instrument in sanitary work was Dr. Scurfield's Ventilation Indicator, showing the ratio of carbonic acid inside and outside dwelling rooms. The stall of the Sanitas Co. (Bethnal-green, E.) was loaded with the great number of disinfectants, antiseptics, and disinfecting appliances now associated with this firm. In addition to the many excellent preparations of which the pleasant and active compound Sanitas is the basis there were shown also the convenient Sulphur Fumigating Candles, Mercuric Bactericide, and "Okol," a powerful and comparatively non-poisonous germicide and a coal-tar derivative. We have already referred in our analytical records to the somewhat remarkable claims put forward by the Amiral Soap Syndicate, Ltd. (28A, Basinghall-street, E.C.), in favour of Amiral Soap. Its application is said to lead to a distinct reduction of adipose tissue. It contains, as we have shown, the active physiological ingredients of ox-gall. The comparatively new antiseptic and disinfectant, Izal, the special medical preparation of which is stated to be four times as strong as absolute phenol, is increasing in favour. At the stall represented by Messrs. Newton, Chambers, and Co., Ltd. (Thorncliffe, near Sheffield), the following Izal specialities were shown: the izal vaporiser, pure izal oil, izal surgical dressings, and izal toilet preparation. Not the least advantage of izal is that though a powerful germicide it is practically non-poisonous. The interesting substance Formalin was exhibited in several forms by the Formalin Hygienic Co., Ltd. (9 and 10, St. Mary-at-Hill, E.C.). Paraform tablets are especially convenient for obtaining the formic aldehyde gas for disinfecting purposes. These are used in conjunction with the "alformant" lamp. For disinfecting on a large scale Trillat's autoclave may be employed, the gas being generated from a mixture of formalin and chloride of calcium (formochloral). Lastly, "glutol" is an antiseptic powder for dressing wounds and is described as the condensation product of formic aldehyde with gelatin. Some very useful Sanitary Soaps were presented for inspection on the stall of Messrs. Price's Patent Candle Co. (Belmont Works, Battersea, S.W.). Thus there were in addition to glycerine soaps combined with well-known antiseptics "Price's Surgeon's Soap" for use in gynæcology. It contains 2 per cent. corrosive sublimate combined with certain aromatic antiseptics, such as thymol and gaultheria, &c. The "aseptic soap" offered by this firm contains also aromatic antiseptics and is extremely pleasant to use. "Creolin" is a well-known disinfectant and antiseptic, the derivation of the word being obvious. The Jeyes' Sanitary Compounds Co., Ltd. (64, Cannon-street, E.C.), were the pioneers of this class of compound, which has now been applied to a great variety of useful purposes. Thus on the stall, which was admirably planned, were besides the ordinary creolin compounds, creolin surgical dusting powder, creolin capsules, and creolin gauze. "Antiseptic preparations" formed an important group in the exhibit of Messrs. C. J. Hewlett and Son (40 to 42, Charlotte-street, E.C), amongst them being a disinfecting fluid of powerful germicidal properties, which while more powerful than carbolic acid, is in comparison with it practically non-toxic. Further obviously useful preparations are also the Antiseptic Jellies, Pellets, and Cream. Not far off was the Ronuk Sanitary Polish (Ronuk, Ltd., 84, North-street, Brighton). This preparation was by no means out of place in the Museum, since it is admirably adapted as a sanitary polish for the flooring of hospital wards. It contains certain aromatics which impart a pleasing, wholesome odour to the surroundings. Lastly, under this section may be mentioned the exhibit of Messrs. Tidman and Sons, Ltd. (Bushell-street), which was devoted mainly to their well-known Sea Salt, which is said to have been the first offered to the public for bath purposes. In the same group was a soap which is compatible with salt or hard water and an antiseptic soap containing salicylic acid in conjunction with other agents as its antiseptic basis.

IV.—Surgical Instruments and Appliances.

This was a department which served eminently to illustrate the remarkable advances of surgery in recent years. The perfection of detail and of design in the instruments at the disposal of surgeons has helped in bringing to a successful issue some of the wonderful surgical achievements of the day. The excellent display of surgical requisites, besides offering a field of instruction, served well from the mere point of view of decoration to relieve the lines of bottles and packets on the other stalls. Considerable discretion had evidently been exercised in separating, as far as conveniently could be done, the exhibits of a like character; and steel instruments, chemical apparatus, electrical apparatus, and so on, were employed usefully and artistically in filling the gaps. A very interesting apparatus, and one which aroused considerable curiosity and attention, was that demonstrated by Dr. Robertson of Cincinnati at Messrs. Allen and Hanbury's stall (48, Wigmore-street, W.). It consists of what is called "the Pneumachemic Comminuter and Compressed Air Apparatus." A number of aspirating globes are situated upon the top of an air container, which is charged by means of an air pump. The globes contain various medicaments of value in the treatment of the respiratory organs. The apparatus effects the vaporisation of these as a very fine spray which is dry and under perfect control. By an ingenious arrangement of the valves a rapid intermittent current of atomised substances may be administered. Close by was a separate stall of the same firm devoted to an excellent assortment of surgical instruments. Amongst these should be mentioned Hoppe's patent Universal Adjustable Splint, Perforated Metal Splints, Scalpels, and Bistouries, the latter being supplied with plain handles or the improved fluted-edged handles. In the Sanitary Section Messrs. Down Brothers (St. Thomas-street, S.E.) exhibited their well-known Aseptic Furniture for Operation Theatres, including their patent Glass Tables and Operation Tables. On their stall in the main hall was a very large collection of Surgical Instruments, several novelties present securing considerable interest from the professional visitors. Aseptic Operating Tables and a Combined Dental Chair and Surgical Operating Table were the chief features of the exhibit of the Medical Supply Association (Edinburgh and 228, Gray's Inn-road, London, W.C.). An enormous Induction Coil was included accompanied by the usual accessories of x ray work and including some recent developments in practical detail. The Spring Bedsteads for hospital use designed by Mr. Lawson Tait were the special exhibit undertaken by Messrs. George Gale and Sons (Birmingham), while close by Messrs. Billington Brothers (Liverpool) had arranged for inspection several well-designed Beds for the Use of Invalids. Near the same space were examples of Theatre Furnishings by Messrs. Arch. Young and Son (Edinburgh). To return to the main hall the Walker Bed for Insomnia was bound to attract interest since at times it was kept in a very gentle rocking movement by means of simple and easily managed hydraulic machinery. It is said to have been employed with excellent effects in cases of insomnia and restlessness. It is the invention of Mr. J. H. Walker (Hartwood, West Calder). A very interesting collection of Hospital and Invalid Appliances was shown by Mr. W. Martin (121, George-street, Edinburgh). The working of an ingenious apparatus for the production of a purely dry heat by electric current for the alleviation of pain in the case of enlarged or stiffened joints, or in gout, rheumatism, and sciatica, was demonstrated by its designer, Mr. Greville (32, Upper Berkeley-street, W.C.). The apparatus is quite simple to manage and consists of a jacket adaptable to the limbs, abdomen, or neck lined with resistance coils. Any desired temperature may be obtained, that usually employed being near 300° F. Biological and Chemical Apparatus for laboratory use formed the subject of exhibit of Mr. B. H. Baird's stall, and also a variety of Glass Jars for anatomical and other specimens were shown. A large collection of similar appliances, such as preparation jars, pathological trays, botanical jars, and glass urinals, were displayed by Messrs. John Ford and Co., the well-known glass manufacturers and china purveyors, of Edinburgh and 33, Holborn-viaduct, London, E.C. Some excellent Designs in Medical Sprays and Atomisers were shown by Mr. Frank A. Rogers (late Corbyn and Co., 327,

Digitized by Google

Oxford-street, W.) as well as Inhalers, Douches, and Several Pharmaceutical Preparations. Close by were the Optical Instruments and Spectacle Lenses which are a specialty of Mr. George Culver (White Lion-street, Pentonville N.). The Liverpool Lint Co.'s stall (Netherfield-road North, Liverpool) was replete with Lints, Bandages, Padding, and Cotton Wools, all of excellent service for surgical dressing, and as specialities may be mentioned the Carbolised Tow and the Surgeon's Tow. The stall of Messrs. C. T. Maling and Sons (Ford Potteries) was devoted to special hospital and private Nursing Requisites in Earthenware. The Sanitary Preparations of the Sanitary Wood Wool Co., Ltd. (26, Thavies-inn, Holborn-circus, E.C.), are well known and deservedly recognised as valuable absorbents. Amongst those shown were wood-wool wadding and tissue, antiseptic and absorbent, sanitary wood-wool sheets for accouchement, hygienic towelettes, antiseptic sponges, &c. A standard collection of Surgical Instruments (aseptic), Operating Tables, and Theatre Fittings was that of Messrs. John Weiss and Son (287, Oxford-street, W.), and the exhibitors were constantly assured of the interest taken in their exhibits by the attention given to them by medical visitors. What is described as a natural antiseptic and deodorant wool and called Bèraudine was shown applied to a variety of surgical dressings by Messrs. Brion, Paté, Burke, and Co. (15, Walbrook, E.C.). A most comprehensive assortment of special Surgical Appliances, all said to be manufactured in the latest aseptic models, were tastefully arranged on the stall of Messrs. J. Gardner and Son (32, Forrest-road, Edinburgh), and near was a collection of Listerian Surgical Dressings, Gauzes, &c., and Catgut Ligatures and Sutures by Messrs. J. F. Macfarlan and Co. (Edinburgh, and 9 and 11, Moor-lane, London, E.C.). The exhibit includes the well-known specially purified chloroform and ether of this firm. The stall of Messrs. Baird and Tatlock (Edinburgh, and 16, Cross-street, Hatton-garden, London) contained an interesting collection of Bacteriological, Chemical and Physical Apparatus. Amongst these were x ray apparatus and the vacuum tubes of helion and argon used by Professor Ramsay and Lord Rayleigh in their interesting investigations. Mr. Harry Cox, of 10 and 28, Cursitor-street, Chancery-lane, exhibited his well-known effective x ray outfit, including several powerful coils of exclusively English make, and improved fluorescent screens. He demonstrated also a means of intensifying the x ray negative. On the stall were some of the best x ray photographs we have seen. Mr. Cox personally superintends the winding and insulation of his induction coils with very satisfactory results. Moreover they are moderate in price and give a maximum spark length with a minimum of battery power. A novel Design in Hospital Construction was shown by Mr. Henry Greenway. The mode of construction is especially designed for the adaptation of the hospital to receive surgical, medical, or lying-in cases, or to be used as a fever hospital. Further, three kinds of infectious cases can be isolated from each other although admitted in equal or unequal numbers, or the entire range of wards can be used for the reception of patients suffering from one disease alone. The particulars of construction, mode of ventilation, heating, and the means by which the infected air may be rendered innocuous are well worth attention. The designer is the consulting medical officer of health of the county borough of Plymouth. The marvellous tensile strength of Longford wire as applied to a hospital bed carrying one ton weight was shown by the company (Warrington). On the same stall were specimens of Wood's Patent Galvanised Woven Wire Saddles, which are said to prevent saddle-soreness and to reduce vibration to a minimum. Close by were the microscopes and other optical apparatus of Messrs. Ross, Ltd., whose name has long been associated with excellence in manufacture of lenses. Similar apparatus was shown by Mr. J. Lizurs (2 and 4, Maitland-street, Edinburgh), one very interesting exhibit being the "Kromscop" for showing Ives's beautiful method of photography in colours. The Globe Nebuliser for producing a remarkably fine spray was shown in action at the stall of Messrs. Oppenheimer and Co. (Victoria House, Victoria-embankment), a new feature connected with it being a detachable aseptic pneumatic mask, which allows complete sterilisation and thus prevents the communication of infection when transferred from one patient to another. On the same stall was a Universal Vaporiser and a new Hypodermic Case with some important features in design and arrangement. Mr. Schall (55, Wigmore-street, W.) was constantly employed in demonstrating the working of his electrical apparatus for galvanisation, electrolysis, faradaisation, cauterising, &c. The batteries and instruments employed for illuminating the mouth, nose, ear, throat, rectum, vagina, urethra, and bladder were evidently highly appreciated by those interested. Messrs. Harvey Hilliard and Son (7, Nicolson-street, Edinburgh) showed a very wide range of Surgical Appliances, artery forceps (Wakley), craniotomy forceps and ovum forceps being amongst the exhibits. Next was the stall of Messrs. J. B. Hilliard and W. B. Hilliard and Sons (65, Renfield-street, Glasgow), worthy of particular mention being the Talipes Boot of Macewen, the Correcting Boot of McVail, and Hilliards' Spinal Evertor and Artificial Spine. Lastly, the well-known specialties of Messrs. Robinson and Sons (55, Fann-street, Aldersgate-street, E.C.), including their Special Tissue, Gamgee Tissue, Dressings, &c., may be taken as examples of the care which is bestowed by the manufacturers in affording the surgeon every chance of success that is possible as regards the treatment of wounds and suppurating surfaces.

Medical News.

EDINBURGH UNIVERSITY.—The following candidates were successful at the recent first, second, and third professional examinations in Edinburgh University for degrees in medicine and surgery:—

First Professional Examination.—R. G. W. Adams, Lewis Anderson, M. F. Anderson, R. G. Archibald, N. H. Beath, Edward Bennett, William Bennett, William Blackwood, E. A. Braine (M.A.), G. B. Brand, J. G. Briggs, J. E. M. Brown, H. H. Bullmore, C. M. Campbell (M.A.), K. A. Cappie, Alec Carruthers (M.A.), J. W. Cathles, A. M. Caverhill, P. D. Cremona, C. W. C. Crooke, H. L. Cumming, Sam Cunliffe, Jan Dommisse, John Dunlop (with distinction), Percy El-Karey, J. S. Elliott, S. C. Ellison, John Fairbairn, A. N. Fell, B. P. Ghose, C. M. Gillespie, E. C. Gimson, A. M. Gloag, R. G. Gordon, Andrew Grant, J. A. Grey (M.A.), T. B. Hamilton (with distinction), D. J. Hamman, Howard Harding, A. W. M. Harvey, A. W. Hauman, George Henderson (M.A.), Henry Herd, J. T. Hill, T. J. Hofmeyr, R. B. Hole, Matthew Holmes, J. M. Johnstone, J. N. Karma, J. P. Kennedy, Harold Kerr, R. D. Kidd, E. A. King, H. A. Knight, Hermann Kramer, G. I. Lecesne, Norah Lenwood (with distinction), William Lilico, J. C. London, R. C. Low, T. S. M. Lumsden, W. F. MacDonald, George M'Farland (with distinction), I. N. M'Keand, George M'Neill, C. E. Marshall, J. M. Marshall, R. J. Mayberry, E. L. Meynell, Thomas Mill, W. S. Milne, A. M. Moll, G. I. Moriarty, A. E. Morton, R. S. Munro, A. E. Nalborough, Charles Nelson, A. L. Nestor, Claude O'Flaherty, T. H. Osler, T. C. E. Parry, E. P. B. Phillips, J. H. H. Pirie, A. M. Pringle, J. A. Raubenheimer, J. J. Redhead, Charles Reece, A. B. dos Remedios, R. A. C. Rigby, H. H. Robarts, Alexander Rose, F. E. Ross, R. E. Russell, J. S. Sewell, J. J. Shannon, E. S. Sharpe, Meurice Sinclair, W. F. Smeall, J. M. Smith, E. W. Smyth, D. W. Standley, J. P. Steven, H. M. Stumbles, G. A. J. Tait, A. B. M. Thomson, Philip Vickers, J. F. van de S. de Villiers, Edwin Wells, W. C. P. White, Harry Whittaker, George Wight, S. A. K. Wilson (M.A.), and W. Y. Woodburn.

Second Professional Examination.—V. G. S. Adams, Robert Affleck, Henry Alexander, C. H. Allen, E. M. Anderson, M. S. Anderson, W. L. G. Anderson, B. H. S. Aylward, A. J. Baird, F. A. F. Barnardo, M.A., J. H. Bell, L. N. Biggs, Lancelot Bruce, G. B. Butt, Ewen Cameron, J. P. Campbell, G. S. Carey, H. L. Clift, W. J. Collinson, A. D. S. Cooke, Leonard Crossley, G. A. Davidson, Archibald Dods, J. P. Douglas, Edward Ewart, Charles Fraser, Yoshinobu Fukuda, A. W. Fuller, O. A. Gee, J. C. Gilchrist, Norman Glegg, J. L. Green, Robert Hamilton, Frederick Hardie, Eleanor Hodson, L. G. Hood, A. J. Hughes, D. B. B. Hughes, F. F. C. Jagger, J. G. S. Jamieson, M.A., John Jamieson, J. M. Jeffrey, J. C. Kennedy, F. K. Kerr, H. C. Keun, S. M. de Kock, A. C. Lennie, G. H. Lewis, G. A. Lowther, D. J. M'Adam, R. J. M'Clelland, J. G. M'Dougall (with distinction), W. J. M. M'Farlane, W. E. M'Farlane, J. H. M'Kee, J. G. Mackenna, D. M. Macleod, Elizabeth Macrory, K. D. Melville, H. C. Miller, J. B. Milne, M. C. Morgan, Florizel Myers, J. C. Parker, Peterswald Pattison, C. B. Paul, M. C. Pepper, D. E. Pratt, J. B. Primmer, J. R. Prytherch, Samuel Rattray, J. L. Rentoul, O. L. Rhys, C. M. Richardson, C. H. G. Ritter, D. J. Roberts, Alexander Robertson, John Ross, M.A., Richard Rutherford, L. S. Sandeman, J. B. Scott, B.A., S. R. Sibbald, William Sloss, J. A. Smaill, H. O. Smith, H. M. Speirs, A. D. Spence, Bernard Stracey, C. P. Strong, K. H. H. Uffman, N. N. Wade, William Wallace, P. D. Whiriskey, Garnett Wright (with distinction), and J. H. Wrightson.

Third Professional Examination.—F. A. F. Barnardo, M.A., L. D. H. Bough, J. A. Black, H. W. Boreham, J. M. Buist, E. A. Burroughs, G. J. R. Carruthers, Morden Carthew, C. S. Clark, H. E. Coghlan, W. J. Collinson, J. D. Comrie, M.A., B.Sc., S. L. Dawkins, Y. A. Djedjizian, D. R. Evans, D. J. Fergusson, B. K. Goldsmith, C. H. G. Gostwyck, A. N. de Gruchy, George Haddow, W. D. S. Harrison, P. H. Henderson, W. E. Herbert, John Jeffrey (with distinction), H. C. Keun, Clarence King, C. G. S. Leeds, George Lyon (with distinction), W. J. M. M'Farlan, E. W. Martin, E. G. D. Menzies, M. J. Menzies, James Miller, H. A. D. Moore, S. H. Morris, Alexander Mouat, A. C. Neethling, T. E. Richards, David Robertson, A. A. Robinson, William Rogers, J. M. Ross, A. B. Slater,

W. C. Spooner, H. B. Sproat, Bernard Stacy, Koh Leep Teng, George Thomson, W. G. Thompson, J. B. Thorburn, Alexander Tweedie, and W. G. Williams.

APOTHECARIES' HALL OF IRELAND.—At the July Examination the following candidates passed in the subjects indicated:—

Chemistry.—William Long and E. A. Reilly.
Physics.—E. A. Reilly.
Anatomy. — First Examination: E. A. Reilly. Final Examination: W. P. Harding and Lewis J. Farell.
Physiology and Histology.—R. Tichborne.
Forensic Medicine.—Frederick A. Bass.
Hygiene.—Frederick A. Bass and Wm. P. Harding.
R. Tichborne and Wm. P. Harding have completed the second professional examination and Frederick A. Bass has completed the third professional examination.
Conjoint with the Royal College of Surgeons in Ireland.—Final Examination: Edward Patrick Eustace and Philip John Murphy.

At the annual meeting of the Governor and Council of the Apothecaries' Hall of Ireland convened by the Act of Incorporation on August 1st the following were duly ballotted and elected to hold office for the ensuing year ending July, 1899: Governor, Mr. James Raverty; Deputy-Governor, Mr. Hugh A. Auchinleck; Council, Mr. John Evans, Mr. W. Furlong, Dr. T. D. Finucane, Dr. J. A. Johns, Mr. R. Montgomery, Mr. Robert John Montgomery, Dr. Charles F. Moore, Dr. Christopher M. O'Brien, Dr. O'Flaherty, Mr. J. Shaw, Mr. Stritch, Mr. S. M. Thompson, and Mr. C. R. C. Tichborne; Representative on the General Medical Council, Mr. C. R. C. Tichborne; Secretary, Mr. Robert Montgomery.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bordeaux:* Dr. Lefour, *professeur-agrégé*, has been appointed to the chair of Clinical Midwifery.—*Cairo:* Dr. S. G. Toller has been appointed Professor of Medicine and Dr. Madden and Mr. Milton, Professors of Surgery.—*Granada:* Dr. Antonio Amor y Rico has been appointed Professor of General Pathology and Dr. Josó de Paso y Fernandez Calvo Professor of Hygiene.—*Lille:* Dr. Charmeil, *professeur-agrégé*, has been appointed to the chair of Clinical Dermatology and Syphilis; Dr. Calmettes has been appointed to the chair of Bacteriology and Experimental Therapeutics.—*Ohio Medical College:* Dr. B. K. Rachford has been appointed Professor of Materia Medica and Therapeutics in succession to Dr. Nieldes, who retires with the rank of Emeritus Professor; Dr. Poole, Professor of Chemistry, has been appointed to the Chair of Physiology.—*Philadelphia Medico-Chirurgical College:* Dr. G. M. Boyd has been appointed Professor of Clinical Midwifery.—*Siena:* Dr. Andrea Cristiani has been recognised as *privat-docent* of Psychiatry.—*Utrecht:* Dr. Katherina von Tusschenbroek has been appointed to the Chair of Gynæcology.—*Würzburg:* Dr. Richard Geigel has been appointed Extraordinary Professor of Balneology.

PRESENTATION TO A MEDICAL MAN.—Mr. J. J. McGrath, L.R.C.S. Irel., of Lower Mount-street, Dublin, was presented by his many friends on July 21st, on the occasion of his marriage, with an illuminated address setting forth the esteem in which he is held and also with a silver tea and coffee service.

LIME WATER.—At the Caerleon (Monmouthshire) Petty Sessions on July 29th a grocer was fined £4 10*s.*, including costs, for selling lime water deficient in lime. The county analyst stated that the water should have contained twice the amount of lime that he had found in it.

GREAT NORTHERN CENTRAL HOSPITAL.—Sir John Dickson Poynder, Bart., M.P., has been elected chairman of the Committee of Management of the Great Northern Central Hospital, in succession to the late Mr. C. T. Murdoch, M.P.

THE VACCINATION QUESTION.—At the meeting of the Plympton (Devon) Board of Guardians held on July 29th it was decided, by 15 votes to 9, on the motion of Mr. C. Aldridge, M.D., C.M. Aberd., L.R.C.P. Lond., that the board were in favour of the compulsory clause in the Vaccination Acts still operating.

EMSWORTH VICTORIA COTTAGE HOSPITAL.—On July 23rd this memorial of the Queen's Diamond Jubilee was opened by Sir Samuel Wilks, Bart., M.D. Lond., F.R.S., President of the Royal College of Physicians of London. Since 1887 the work has been carried on in a cottage with 4 beds, rented at £16 a year. Over 300 in-patients have been treated, 54 of whom were suffering from accidents, and 46 operations have been performed, and this without incurring any debt. For the last three years the average cost per head per day, including maintenance, nurse, and rent, has been 2*s.* The present hospital for seven beds, designed by Mr. John Birch, 8, John-street, Adelphi, has been erected at a cost of £1500 and is very convenient in its arrangements. It consists of a first floor on which are two wards of three beds each and the matron's bedroom, and a second floor with a small special ward of one bed, bathroom, servants' room, and operating-room, admirably lighted and equipped. The honorary consulting staff are Dr. Goodhart and Mr. W. H. A. Jacobson; the honorary medical officer is Mr. Lockhart Stephens. After a careful inspection Sir Samuel Wilks expressed his entire approval of the design and arrangements.

ASSAULT ON A MEDICAL MAN.—Mr. Richard Harding, L.R.C.P. Edin., L.F.P.S. Glasg., vice-chairman of the Radnorshire County Council and medical officer of health of the New Radnor Rural District Council, was violently assaulted on the evening of Aug. 1st. Mr. Harding was riding a bicycle to visit a patient, when the lamp went out and he went to a cottage to endeavour to get a light, but being unable to make anybody hear was turning away when he was attacked from behind and seriously injured. Medical aid was fortunately obtained. An arrest has been made.

THE Eleventh Universal Cookery and Food Exhibition will be held in the galleries of the Imperial Institute in the month of March, 1899. The exhibition will, as heretofore, be under the auspices of the Universal Cookery and Food Association, and the chairman of the Executive Council of the Exhibition will be Mr. J. C. Buckmaster, whose association with the cause of cookery is historical. The offices of the Executive Council are 329, Vauxhall-bridge-road.

LUNACY IN DORSETSHIRE.—Although the new county asylum at Charminster has only been completed about two years the Dorset County Asylum Committee has been informed by the Commissioners in Lunacy that owing to the increase of lunacy the available accommodation will be exhausted in five years, and the county is asked to take the matter into early consideration in view of making additional provision. During the past year the percentage of new admissions has been very high.

MR. J. A. CAMPBELL, M.D., C.M. Glasg., F.R.S. Edin., on his recent retirement after over thirty-one and a half years' service as a medical officer and upwards of twenty-five years as medical superintendent of the Counties Asylum at Carlisle, has been appointed an honorary consulting physician to the institution; and Mr. W. F. Farquharson, M.B., C.M. Edin., after seven years' service as a medical officer to the asylum, has been promoted to the office of medical superintendent.

MORETONHAMPSTEAD CONVALESCENT HOME.—The new wing of the Moretonhampstead Convalescent Home was opened on Aug. 3rd by Mrs. Mallock. This home, founded by the Misses Phillips in 1872, at first had only accommodation for 14 people, but it was enlarged in 1879. Last year 156 patients were admitted. The new wing has been erected at a cost of about £800, of which sum the Misses Phillips have subscribed £300. About £200 is still required to free the home from debt.

MONMOUTHSHIRE COUNTY COUNCIL.—At the meeting of the Monmouthshire County Council held on Aug. 3rd it was resolved, on the motion of Sir Henry Jackson, Bart., to appoint a committee for the purpose of acquiring the historic ruins of Tintern Abbey and Raglan Castle for the county.—At the same meeting it was stated that temporary buildings were to be added to the county asylum to accommodate 50 patients of each sex. The cost of the erection would be £3400 and the furnishing £1494 in addition.

CORPORATE AND MEDICAL REFORM ASSOCIATION, LIMITED.—At a recent local meeting at Oldham of this association, Dr. James Corns (Oldham) being in the chair, in addition to the chairman and Mr. Platt, J.P., Mr. Martland, Mr. Fort (honorary secretary), Mr. Kershaw, Dr. Lendrum, and Mr. W. B. Yates were appointed members of the Oldham Local Committee. It was resolved prior to the

Digitized by Google

great Lancashire centres being approached in favour of the promotion of a County of Lancashire Branch of the Association to take active measures in Oldham and the neighbourhood to propagate the policy and extend the membership of the association and to hold a general meeting after the holidays.

CONGRESS OF HYDROLOGY, CLIMATOLOGY, AND GEOLOGY.—The fifth International Congress on Potable Waters, Mineral Waters, and Medical Climatology and Geology will be held at Liège from Sept. 25th to Oct. 3rd under the patronage of the Crown Prince of Belgium. There will be receptions by the municipalities of Liège, Spa, and Aix-la-Chapelle, and visits will be paid to various places, including Ostend, Middelkerke, and Wenduyne. The congress committee will be pleased to offer to all the foreign members a free railway-ticket throughout the whole of Belgium for this Ostend excursion from Liège. Members will obtain a reduction of 50 per cent. on all railway fares throughout Belgium. The subscription to the congress is 16*s.* for gentlemen and 8*s.* for ladies and university students. Communications intended for the congress should be sent before Aug. 25th to Dr. G. Jorissenne, general secretary, 130, Boulevard de la Sauvenière, Liège, Belgium.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, AUGUST 4TH.

The Preparation of Calf Lymph.

MR. HEDDERWICK asked the President of the Local Government Board whether the calves from which the lymph was to be derived, under the provisions of the Vaccination Bill, would be slaughtered after use and the carcasses exposed for sale in the meat markets.—MR. CHAPLIN replied: I have already stated more than once that every calf used for the preparation of glycerinated lymph will be subsequently slaughtered and no lymph will be issued until both the carcass and the internal organs have been inspected by the veterinary surgeon attached to the slaughtering establishment and have been reported to be in every respect healthy. In all countries in which calf lymph has been in use during the past quarter of a century such healthy carcasses are exposed for sale, and I am not aware of anything at present that would make a different course necessary in this case.

Nursing in Workhouse Infirmaries.

MR. TALBOT asked the President of the Local Government Board what progress had been made in carrying out the requirements of the Board expressed in their orders of August, 1897, urging boards of guardians to employ trained nurses only in their infirmaries; and whether it was within the knowledge of the Board that many boards of guardians had found great difficulty in obtaining the services of such nurses; and, if so, what steps the Local Government Board proposed to take to supply them.—MR. CHAPLIN replied: The order of August, 1897, provides that no person shall be appointed to the office of nurse without having had such practical experience in nursing as may render her a fit and proper person to hold the office. Since the issue of the order there has been a decided improvement in the nursing arrangements in many of the workhouses and of the nurses appointed an increasing number have been trained. I am aware that in consequence of the great demand for duly trained nurses many boards of guardians have found difficulty in obtaining the services of such nurses. The Local Government Board, however, have neither the duty nor the power to supply nurses for workhouses, but they are encouraging the training of probationer nurses at workhouses where adequate arrangements exist, who will increase the available supply in the future.

The Medical Officer of the Factory Department.

MR. TENNANT asked the Home Secretary whether he would inform the House what the duties of the new medical officer of the Factory Department would be and whether he would lay upon the table the instructions under which that officer would act and whether he had yet made the appointment.—Sir M. WHITE RIDLEY said in reply: I settled these instructions some weeks ago and shall be glad to state their effect. Briefly they are as follows. The medical inspector will reside in London and his services will be available throughout the country wherever they are required. He will conduct special and general inquiries into questions of health and safety as the chief inspector may direct; he will exercise general supervision over the work of certifying surgeons, especially where they have duties with regard to dangerous industries; he will deal with the notices of lead and other poisoning received under the Act of 1895; he will advise the staff generally on all medical questions connected with their work and will give evidence in proceedings when so directed by the chief inspector, though he will not himself institute prosecutions unless specially directed. In visiting factories, workshops, and other places he will give special attention to all matters affecting the health and safety of the persons employed; he will supply to the district inspectors particulars of any irregularities, defects, or infringements of the Acts which he may observe and also particulars of any recommendations he may make to occupiers, and he will call the special attention of the district inspectors to cases where he considers any structural alteration necessary or a prosecution desirable. He will also visit hospitals in places where industrial diseases prevail and, generally, he will act in coöperation with the other members of the staff, the certifying surgeons, and the local authorities. I have appointed to the office Dr. Thomas Morison Legge.

Water-supply of Deal.

MR. CHAPLIN, answering a question addressed to him by DR. TANNER, said that the local authorities of Deal and Walmer had recently acquired the waterworks undertaking and were extending their mains throughout the whole district. Notices had been given to all persons having wells on their premises to discontinue the use of the wells and to lay on the water from the waterworks. Where these notices were not complied with and where the water had been found to be impure the wells had been closed and the premises connected with the waterworks main.

MONDAY, AUGUST 8TH.

Tuberculosis Commission.

MR. CHANNING asked the President of the Local Government Board whether he had now considered the portions of the report of the Tuberculosis Commission dealing with the supply of milk and the urgent necessity for strengthening and facilitating the operation of the Dairies, Cowsheds, and Workshops Order, 1885-86, with a view to secure uniformity of action and for extending the powers of local authorities to inspect dairies and byres; and whether he would by administrative order effect immediately such administrative checks to the mischiefs now existing as were possible and proceed next session to ask for the extension of the powers of the department and of local authorities as were necessary to reduce the risk from tuberculosis in milk to a minimum.—MR. T. W. RUSSELL replied to the question, saying: The numerous questions which are raised by the report of the Royal Commission on Tuberculosis are now under the consideration of the Government, both with regard to administrative orders and to legislation if necessary.

TUESDAY, AUGUST 9TH.

The Vaccination Question in Scotland.

DR. CLARK asked the Lord Advocate whether he was aware that there had been a considerable increase of vaccination prosecutions in Scotland and that the Court of Session had decided that defaulters might be summoned every six months until the child was fourteen years old; and whether it was the case, as stated at the Dundee Sheriff's Court last week, that instructions were sent out in May by the Local Government Board, Scotland, directing prosecutions.—The LORD ADVOCATE replied: I am informed by the Local Government Board that they are not aware that there has been any such increase of vaccination prosecutions in Scotland as is suggested in the question. The Court of Session has decided that defaulters may be prosecuted so long as their names appear in the half-yearly lists transmitted by the registrars to the parochial boards (parish councils); but the Board have advised parish councils that they may use their discretion in repeating prosecutions in respect of the same child. The Local Government Board have issued no general instructions as to vaccination prosecutions. On May 28th last they inquired of the inspector of poor, Dundee, how his parish council proposed to deal with defaulters and were informed that the parish council had resolved to prosecute.—MR. DALZIEL asked the Lord Advocate whether, in view of the legislation which had been passed this session in reference to compulsory vaccination in England, the Government would consider the advisability of suggesting to the Local Government Board in Scotland the desirability of refraining from active prosecution of conscientious objectors.—The LORD ADVOCATE replied: As I have already stated in this House the system as regards vaccination in Scotland has hitherto worked successfully and the Secretary for Scotland does not consider that any special suggestion need be made to the Local Government Board on the subject.—MR. DALZIEL asked whether, in view of the fact that several persons were in prison in Scotland, the Government intended to allow the conscientious clause to prevail in England and at the same time to continue prosecutions in Scotland.—The LORD ADVOCATE replied: The Government intend to maintain the law in Scotland, as it is the law. Of course, if the law is altered it must be altered by Act of Parliament, but in the practical working out of the law there has never been any difficulty in Scotland, and I would hope that there would not be imported into Scotland an agitation which must be of an exotic character.—DR. CLARK asked whether there could be prosecutions in Scotland except by the Lord Advocate or his deputies.—The LORD ADVOCATE replied: Yes, there can be prosecutions by others.

Medical Aid for the Khartoum Expedition.

MR. H. J. C. MORTON asked the Under Secretary of State for Foreign Affairs whether Her Majesty's Government would advise His Highness the Khedive to grant permission to the British Red Cross Society and to members of the Order of St. John of Jerusalem to accompany the Khartoum Expeditionary Force at their own expense for the purpose of rendering medical aid to the wounded without distinction of race, colour, or creed.—MR. CURZON replied that the military authorities in Egypt had gladly accepted the assistance of the Red Cross Society for work between Cairo and Assouan. The difficulties of transport, any further call on which would diminish the numbers of the fighting force,

Digitized by Google

made it impossible, in the opinion of the authorities, to accept any offers of assistance above Assouan.

WEDNESDAY, AUGUST 10TH.

Metropolitan Hospitals and Midwifery Cases.

MR. ARTHUR O'CONNOR asked the Home Secretary whether he was aware that a poor woman expecting confinement frequently applied to one or other of the general hospitals in London for a doctor to attend her in her confinement, and that frequently in such a case a student was sent to attend who had little or no experience, or might even never have been in a case before, and that no intimation was in such case given to the patient that the person sent was not a fully qualified medical practitioner; and whether the General Medical Council had prohibited the employment by private practitioners of assistants who, although they had taken out a full course of midwifery training, had not taken out a degree in medicine, surgery, and midwifery.—Mr. JESSE COLLINGS replied: The Home Secretary has no information on the subject, but he will communicate with the General Medical Council and make further inquiries so as to ascertain the facts of the case.—Mr. O'CONNOR: May I ask whether besides the inquiries he has promised to make the Home Secretary will further inquire whether among the members of the General Medical Council itself there are gentlemen who are medical officers attached to the hospitals from which these unqualified persons are sometimes sent and whether the Privy Council is in a position to require the General Medical Council to enforce its own regulations for all parties?—Mr. JESSE COLLINGS: There will be a full inquiry made.

PROCEEDINGS ON THE VACCINATION BILL.

HOUSE OF LORDS.

THURSDAY, AUGUST 4TH.

The Vaccination Bill was considered in the House of Lords at this sitting on the order for taking the Committee stage.

The Marquis of AILESBURY moved that the House do resolve itself into Committee on the Bill on this day three months, or, in other words, moved the rejection of the Bill. His lordship complained that the Bill was badly drafted, that it made no allusion to revaccination, that it contained no safeguards, and that it seemed to embody the open-door policy in the matter of small-pox.

Lord LISTER next addressed the House in support of the Bill. A verbatim report of his speech will be found on p. 426.

The Earl of PORTSMOUTH appealed to the Marquis of Ailesbury to withdraw his motion and allow the Bill to be considered in Committee.

Lord HARRIS said he had authority to intimate that the Government were prepared to consider during the recess whether it would not be possible to bring in next session a Bill dealing with revaccination.

The motion of the Marquis of Ailesbury was then negatived without a division and the House went into Committee on the Bill.

The Earl of FEVERSHAM moved to delete Clause 2, the clause dealing with the conscientious objector, arguing that with this clause in the Bill there was no security against small-pox.

Lord ALDENHAM spoke in support of the deletion of the clause.

Lord HARRIS defended the clause on the ground mainly that it embodied a recommendation of the Royal Commission.

Lord LOCH expressed the view that with the new form of lymph the objection to vaccination would disappear.

After a speech from the Marquis of SALISBURY in support of the clause a division was taken, when 40 members voted for the omission of the clause and 38 against that motion. The clause was accordingly removed from the Bill.

FRIDAY, AUGUST 5TH.

When their lordships met to-day they received the amendments made in Committee and read the Bill a third time.

MONDAY, AUGUST 8TH.

At this sitting a message from the House of Commons was read stating that the Commons had disagreed with the Lords' amendment striking out Clause 2, the reasons given being that unless some provision were made for those who conscientiously object to vaccination the enforcement of vaccination would be impracticable in many districts and that the amendment of the Lords was not in the interests of the promotion of vaccination.

Lord HARRIS moved that their lordships do not insist on the amendment.

Lord ROOKWOOD condemned the clause as subversive of good government.

Viscount GALWAY insisted that the Government had given no good reason for the clause.

Lord ZOUCHE advocated the postponement of the Bill until next Session.

Lord STANMORE argued that the Government had power to pass the Bill as they originally proposed it and urged them to exercise their power.

Lord GLENESK, the Earl of FEVERSHAM, Lord ALDENHAM, and the Earl of PORTSMOUTH also spoke against the clause.

The Marquis of SALISBURY then addressed the House. He reviewed the action of the House of Commons on the Bill and spoke at length on the indisposition of many local authorities to enforce the existing law and concluded with these words—viz.:—My lords, I do not look to the effect of this except in one direction; I ask, What effect will it have upon that willing adoption of vaccination which is the only healthy result which you can desire to accomplish? If you pass this Bill now there is nothing whatever, supposing the difficulties about the conscientious objector turn out to be real, to prevent your having another Bill to strengthen what may be thought to be too weak in this Bill. But, at all events, you will have offered an opportunity to those who say your coercion is a mistake and you will have given an experimental trial to those improved processes by which you hope the popular illusion will be dissipated; you will have had a truce and an armistice, the bitterness will have calmed, and the agitation will have gone down, and you will be able to induce local authorities to work with you instead of against you in carrying out this great enterprise for the health and welfare of the people. My lords, I think that the advice which has been given to you under all the circumstances—I do not look beyond that—to kill the Bill is very unwise advice; and for the sake of your own opinion, for the sake of the reform of the law, for the sake of the ultimate achievement of united action upon a matter in which union and concord are essential, you ought to forego the amendment which you only passed by a majority of two three nights ago and allow the Bill to pass into law.

When a division was taken the motion of Lord Harris was carried by 55 to 45 votes. The result is that the clause remains part of the Bill.

HOUSE OF COMMONS.

FRIDAY, AUGUST 5TH.

At a late hour at this sitting the Commons considered the amendments made by the Lords.

Mr. CHAPLIN moved that the House disagree with the Lords in striking out Clause 2, dealing with the conscientious objector.

Mr. GRANT LAWSON expressed his approval of the action taken by the House of Lords in this matter.

Mr. MONK spoke of the clause as practically repealing the Vaccination Acts.

Mr. GRIFFITH-BOSCAWEN recommended the Government to take this opportunity of repairing what he regarded as an unfortunate error.

Mr. CHAPLIN defended the action of the Government saying among other things that the state of opinion in the House of Commons left no other course open to the Government. He predicted that if the Bill were lost there would be a state of things bordering on chaos.

When the division was taken the motion of Mr. Chaplin was carried by 129 to 34 votes.

Accordingly the clause was reinserted in the Bill and a committee was appointed to draw up reasons for disagreeing with the House of Lords.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BURGES, F. A. L'ESTRANGE, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Handsworth and Great Hampton-street Division of the Post Office.

DOWNMAN, C. F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Burnham-on-Crouch Urban District Council.

DUNCAN, WILLIAM, M.B., C.M. Glasg., has been appointed Medical Officer of Health for the Clay Cross Urban District, vice Angus Mackintosh, deceased.

FORBES, D. McD., L.R.C.P. F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Eastwood Urban District Council.

FRASER, D., M.D. Glasg., F.F.P.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Burgh of Paisley.

FREER, J. H., L.R.C.P. Lond., M.R.C.S., has been re-appointed a Medical Officer by the Rugeley Urban District Council.

GRAHAM, T., M.D. Glasg., L.F.P.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Burgh of Paisley.

HAYDON, H. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Wadebridge Sanitary District of the Bodmin Union.

JONES, T., M.R.C.S. has been appointed Medical Officer for the Middle District of the Whitechapel Union, vice J. Sequeira, resigned.

LEGGE, T. M., M.D., B.Ch. Oxon., D.P.H. Camb., has been appointed Medical Inspector of Factories and Workshops.

LUNAN, C. S., M.B., C.M. Edin., L.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Sheriffdom of Perth.

MASTER, GEO., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Medical Officer for the Suffolk General Hospital, Bury St. Edmunds, vice J. S. Hinnell.

OULTON, H. W., M.D. Dubl., L.R.C.S. Irel., has been appointed a Surgeon to the Dublin Metropolitan Police Force, vice T. Nedley.

PARSON, WM., M.R.C.S., has been re-appointed Medical Officer for the Godalming Sanitary District of the Guildford Union.

PLUMMER, H. B. W., M.D. Durh., M.R.C.S., has been appointed an Honorary Consulting Surgeon for the West Bromwich District Hospital, vice H. Sutcliffe, resigned.

ROBERTSON, J. F., M.D. Edin., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Shetland.

SHACKEL, G. A., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Ludlow Rural District Council.

VERNON, C. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Ashford Urban Sanitary District.

WHITE, H. E., L.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Medical Officer for the Infirmary of the Parish of Birmingham.

Digitized by Google

WILLIAMSON, J., M.R.C.S., L.R.C.P., has been appointed a House Physician for the General Infirmary, Leeds.

WILKINSON, GEO., B.A., M.B. Cantab., F.R.C.S., has been appointed an Honorary Surgeon to the Royal Hospital, Sheffield, vice Sinclair White.

WILKS, T. H., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Medical Officer for the Sheffield Children's Hospital, vice J. B. Milne, resigned.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £70, with board, residence, and washing.

CARNARVONSHIRE AND ANGLESEY INFIRMARY AND DISPENSARY, Bangor. House Surgeon. Salary £70 per annum, with board and lodging in the house.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, increasing £10 yearly to £120 per annum, with board, lodging, washing, and attendance.

COUNTY ASYLUM, Gloucester.—Locum Tenens for about two months. Salary £2 2s. per week and all found (except liquors).

CUMBERLAND AND WESTMORELAND ASYLUM, Carlisle.—Senior Assistant Medical Officer. Salary £120 a year, with board. Applications to Dr. Farquharson, Garlands, Carlisle.

CUMBERLAND INFIRMARY, Carlisle.—Assistant House Surgeon for seven months from Oct. 1st to April 30th. Salary at the rate of £40 per annum, with board, lodging, and washing. Also House Surgeon for one year. Salary £70 per annum, with board, lodging, and washing.

DERBY COUNTY ASYLUM, Derby.—Second Assistant Medical Officer, unmarried. Salary £100 per annum, rising to £120, with board, lodging, and washing.

DEVON COUNTY ASYLUM.—Medical Superintendent. Salary commences at £800 per annum, with other emoluments. No domestic or other servants provided. Applications to the Clerk to the Visiting Committee, 9, Bedford-circus, Exeter.

DEVONSHIRE HOSPITAL, Buxton.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E. — Unqualified Clinical Clerkships, tenable for three months.

GUEST HOSPITAL, Dudley.—Resident Medical Officer. Salary commencing at £100 per annum, increasing by £10 a year to £120 (conditionally), with board, residence, attendance, and washing.

HUDDERSFIELD INFIRMARY.—Senior Assistant House Surgeon. Salary £50 per annum, with board, residence, and washing. Also Junior Assistant House Surgeon. Salary £40 per annum, with board, residence, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence in the institution.

MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road. — House Surgeon. Salary £80 per annum, with apartments and board.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Resident Medical Officer for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

Births, Marriages, and Deaths.

BIRTHS.

CURRIE.—On Aug. 5th, at Edinburgh, the wife of Oswald James Currie, M.B., M.R.C.S., Maritzburg, Natal, of a son.

GODDARD.—On Aug. 6th, at Pentonville-road, N., the wife of Bertram Goddard, L.R.C.P. Lond., &c., of a son.

HARPER.—On July 29th, at Grosvenor-place, Bath, the wife of J. Maurice Harper, M.R.C.S. Eng., of a daughter (stillborn).

REID.—On Aug. 5th, at Thirlmere, Watford, the wife of A. Lestock Reid, M.R.C.S., L.R.C.P., of a daughter.

STEPHENS.—On July 30th, at The Lindens, Doddington, Cambs, the wife of Cecil Edward Stephens, M.B., of a son.

TINLEY.—On July 28th, at Thorsgrif, Whitby, the wife of W. E. F. Tinley, M.B. Durh., M.R.C.S., of a son.

MARRIAGES.

ATKINSON—EASTMOND.—On Aug. 3rd, at St. John's Cathedral, Hong-Kong, by the Rev. R. F. Cobbold, M.A., John Mitford Atkinson, M.B. Lond., Principal Civil Medical Officer, Hong-Kong, son of the Rev. S. Atkinson, M.A., of Portland, to Clara, eldest daughter of James Eastmond, of Puddyngton, Devonshire.

MACDONALD—STEWART.—On Aug. 8th, at Kenneth-street, Stornoway, Catherine Mary Stewart, daughter of the late John Stewart, of Holm, Stornoway, N.B., to John Smyth Macdonald, B.A. Cantab., L.R.C.P., L.R.C.S., of University College, Dundee, son of George Macdonald, of Chester.

PILLOW—WRIGHT.—On Aug. 10th, at St. Mary Abbott's, Kensington, Henry Pillow, M.D., Pembridge-gardens, W., to Marie Helen Wright, youngest daughter of the late James Wright, Aughantaraghan, co. Armagh.

WARD—JEFFERIES.—On Aug. 4th, at St. Helen's, Ipswich, Francis Ward, M.D., eldest son of Colonel A. E. Ward, late Bengal Staff Corps, to Elizabeth Lilian, second daughter of John Robert Jefferies, J.P., of St. Helen's Lodge, Ipswich.

DEATHS.

ACKLAND.—On Aug. 7th, at Fairhaven, Upper Compton, Plymouth, William Henry Ackland, M.D., J.P., in his 73rd year.

MILTON.—On Aug. 3rd, at Sion House, Chelsea, John Laws Milton, M.R.C.S., of Suffolk-street, Pall-mall.

ROBERTS.—On Aug. 5th, of tubercular meningitis, John Hamilton Roberts, a medical student of Charing-cross Hospital, the only son of J. T. Roberts, L.R.C.P. Edin., 65, Park-road, Crouch-end, in his 20th year.

SMITH.—On Aug. 10th, at "Yew Tree," Lewisham, Frederick Henry Smith, M.D., aged 62 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

STERILISATION OF ELASTIC CATHETERS.

IN the current number of the *Deutsche Medicinische Wochenschrift* Dr. Oscar Ehrmann of Mannheim describes two pieces of apparatus which he has devised for the sterilisation of elastic catheters by passing a current of steam through them. He states that for good elastic catheters sterilisation by steam is less injurious than any other equally efficient method, but the apparatus for this purpose described by Posner and Kutner is complicated and costly. He has therefore designed an appliance which may be worked in connexion with any ordinary steriliser. It consists of a boiler provided with several steam jets for insertion into the open ends of the catheters which lie on a perforated tray and are surrounded by the steam filling the closed steriliser so that they are thoroughly exposed to the steam both inside and out. The other apparatus, which is intended for the use of patients, is on the same principle, but is heated by a spirit lamp and takes in only one catheter at a time. The whole of it can be packed into a space 3¾ in. high and 2¾ in. in diameter. The maker is Mr. Walb of Heidelberg.

ANTI-RHEUM.

A CORRESPONDENT sends us the following circular which he has received and which we think registers a high level of impudence:—

Strictly Confidential.

51, Glasshouse-street, W., 5th August, 1898.

My dear Sir,—We are collecting testimonials from the medical profession for a valuable specific for rheumatism. ANTI-RHEUM has been tried at all stages of this distressing complaint and has in all cases proved an undoubted success. We send you a sample under separate cover.

Testimonials should be sent in before the 12th inst. to secure priority in a special allotment of founders' shares reserved for the faculty. We are, dear Sir, your obedient servants,

STONEFIELD PRATT AND CO.

INSTRUCTIONS FOR USE.

Dissolve in hot water and use as a fomentation.
Packet containing 2 oz. price one shilling.

Our readers will note the suggestion that the medical man should hurry up with his testimonial if he wants to get a special allotment of shares!

AN OPERATION IN A HOSPITAL BY AN UNQUALIFIED PERSON.

THE French press reports a somewhat curious action in the civil courts in which the plaintiff was the father of a child who had been circumcised in a Bordeaux hospital and the defendant the surgeon in whose service the operation was performed. The complaint was that it had been unskilfully carried out, so that "an infirmity" had resulted, and damages were claimed against the surgeon, who, it appeared, had not actually performed the operation himself, but had allowed a person who was not even a medical student to perform it in his presence. This person was a Jewish official, a candidate for the office of circumciser, who had applied to the defendant for a certificate of competency. The defendant had examined him and had seen him operate on the dead body. In addition he arranged to allow him an opportunity of operating on a living child—not a Jew—in the hospital, with the result of landing himself in a somewhat unpleasant position in a court of law. The view of the court was apparently that by delegating his functions as surgeon to an unqualified person who was not even a medical student he had acted illegally. A committee of experts was, however, appointed to examine the child as to the alleged "infirmity."

A WARNING TO MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—As a protection to the members of the medical profession, I beg to inform your readers that the General Accident Assurance Corporation, Limited, has no agent or person of any kind authorised to appoint medical referees, all such appointments being made by my board and from this office direct. The necessity for this letter has arisen through medical men in Gateshead, Hull, and other towns having written us that a man, or men, giving various names have called upon them offering the appointment of medical referee for our company and taking the medical men's accident proposals, and with them, a deposit, usually £1, and they, the medical men, have heard nothing further of the matter. It seems to me that this is one man who is travelling from town to town under various names, or a gang of men, who are thus victimising the medical men in various towns, and as it appears they have the prospectuses of this company they must have called on our agents or our branch offices, and asked for copies of our prospectuses for purposes of insurance.

I am, Sirs, yours faithfully,

F. NORIE MILLER,
Manager, The General Accident Assurance Corporation, Limited.

Chief Offices, 42 to 44, Tay-street, Perth, N.B.; 115 and 117, Cannon-street, London, E.C., Aug. 3rd, 1898.

"SANOSE."

BY an obvious printer's error this interesting compound was described in our notice last week of the exhibits at the Annual Museum of the British Medical Association as containing 80 per cent. of casein and 120 per cent. albumose. The last figure should, of course, have read 20 per cent.

WANTED A HANDBOOK ON HYPNOTISM.

To the Editors of THE LANCET.

SIRS,—I should feel obliged if any of your readers could recommend a good work on Hypnotism, one giving practical details as to the production of the hypnotic state would be preferred.

I am, Sirs, yours faithfully,

Aug. 7th, 1898. INQUIRER.

J. D. S.—A correspondent who has personal knowledge of Port Erin and Port St. Mary (Isle of Man) informs us that they are naturally both very healthy towns. They both belong to the peninsular parish of Rushen. Port Erin looks straight towards the west (having Ireland, in the shape of the Mourne mountains, in front of it), whilst Port St. Mary looks out on the sea towards the east mainly, but a large portion of the best new part looks to the south-west over the bay. The populations of these two towns would dominate the death- and birth-rates of the parish of Rushen in which they lie. During 1896, according to the last annual report of the Manx Registrar-General (the one for 1897 will now soon be published), the death-rate for the Isle of Man was 19·2 per 1000 and that for Rushen 19·6. In his inaugural address on Medical Geography, delivered before the Isle of Man Medical Society, and published in THE LANCET of July 31st, 1897, Mr. Alfred Haviland stated that the phthisical death-rate of the island is higher than that of England and Wales. At certain times of the year, when the equatorial winds are strong, phthisical cases cannot stand the Rushen coast and soon fall victims. The water-supply is good in both towns, coming from springs on elevated moorland. In 1896 only two deaths from zymotic disease (one from scarlet fever and one from measles) were registered in Rushen. It must be remembered that the sanitary regulations in the Isle of Man are very different from what they are in England. An Act for notifying disease is in operation and there is an isolation hospital about two miles from Douglas. Aberystwith can be recommended as a health resort.

Medical Referee.—It is undesirable that a medical referee should attend anyone whose case may hereafter come before him in his capacity as medical referee. This ruling, however, would not apply in the case of a patient treated in a hospital gratuitously by a medical officer of the hospital who also may be a medical referee.

S. H. S.—For full information see numerous articles in our columns. Consult the index of vol. 1 of THE LANCET for the current year. THE LANCET of April 23rd, 1898, contains the official memorandum of the Home Office on the subject.

Acute Sufferer should consult his medical man.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested Milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal*, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says:—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

"Does not depress the Heart."

ANTIKAMNIA (C_NH_{2N-6}).

OPPOSED . . . . . TO PAIN.

PROF. H—— E——, A.M., M.D.,

Fellow of the American Academy of Medicine, points out one or two important facts in regard to ANTIKAMNIA. He says:—

"Antikamnia possesses no merit as a preventive of pain; its action is *nil* until the pain begins.

"Antikamnia, when given in five-grain doses every ten minutes until grs. xxx. have been taken, produces no effect whatever in a *healthy* person. As my investigation concerned its action under pathological conditions, I did not inquire further into the question how much more than thirty grains might be administered to a healthy person without any deleterious effect.

"The action of Antikamnia as an analgesic begins the moment an individual is attacked by pain; and here a great number of observations has established with me the following rule for its administration to adults:—

"As early as possible after the pain has developed—if possible, immediately after—Antikamnia grs. v. are taken; from three to four minutes later, if the first dose has no, or but little, effect, the same dose is repeated; and again three or four minutes later, provided again the effect is *nil* or not sufficient, this dose is administered the third time. Then I let the patient wait ten minutes; if by the end of that time the pain be greatly ameliorated but a trace of it still present, a fourth dose of gr. v. then (i.e., ten minutes after the third) given will generally stop the pain completely."

Prof. E——'s observations have been confirmed and reinforced in England by eminent physicians. *See signed reports*, MEDICAL REPRINTS, *January, 1896 and November, 1896.*

EDINBURGH MEDICAL JOURNAL says:

"This is one of the many Coal-Tar products which have lately been introduced into medicine. . . . In doses of three to ten grains it appears to act as a speedy and effective antipyretic and analgesic."

The American antipyretic, anodyne, and analgesic, is a combination of Coal-Tar derivatives of the series CnH2n-6, into which the amines have entered, forming the various amido-compounds.

It has, in contradistinction to other coal-tar products, a stimulating action on the nerve centres and the vital functions, especially the cardiac system.

It occurs in microcrystalline powder, and is perfectly white in colour; of a slight pungently bitter taste and alkaline reaction. It is moderately soluble in water, more freely with glycerine sparingly added, and freely soluble in brandy, whisky, or wines, according to their alcoholic percentage. In liquid prescriptions, however, simple elixirs offer the best vehicles.

ANTIKAMNIA should not be dispensed, however, in any vehicle of acid reaction. It can be readily given in tablets, as well as in powder (dry on the tongue) followed by a swallow of water or wine.

DOSE for Adults—5 to 15 grains; for Children in proportion. As a pain reliever in Neuralgia, Rheumatism, &c., ANTIKAMNIA acts with safety, certainty, and celerity.

PRICE OF ANTIKAMNIA TO THE MEDICAL PROFESSION.—**In three-grain or five-grain Tablets, or in Powder, 3s. 9d. per Ounce. One-ounce packages only. Price to the public (on prescription only), 4s. 6d. per Ounce.**

ANTIKAMNIA COMBINATIONS.—**Antikamnia and Codeine Tablets** (4½ gr. Antikamnia, ¼ g., Sulph. Codeine); **Antikamnia and Quinine Tablets** (2½ gr. Antikamnia, 2½ gr. Sulph. Quinine); **Antikamnia and Salol Tablets** (2½ gr. Antikamnia, 2 gr. Salol).

"Does not depress the Heart."

Digitized by Google

BONE MARROW

acts as a Stimulant to the Formative Processes and increases the production of red blood corpuscles and hæmoglobin, making it the ideal remedy in all diseases due to defective hæmogenesis.

The best results follow the use of a preparation made with Marrow taken from the animal immediately after it is killed.

Glycerine is practically the only medium for preserving the product in an unaltered condition.

ARMOUR'S EXTRACT OF RED BONE MARROW

Is made from absolutely fresh material and pure Glycerine, and contains all the essential ingredients of raw Marrow.

ARMOUR & COMPANY (Chicago), LONDON, S.E.,

Will be pleased to send Samples of this Preparation to Physicians interested, with Reports of Cases successfully treated.

SYR. HYPOPHOS. CO. FELLOWS

CONTAINS THE ESSENTIAL ELEMENTS of the Animal Organisation—Potash and Lime;

THE OXIDISING AGENTS—Iron and Manganese;

THE TONICS—Quinine and Strychnine;

AND THE VITALISING CONSTITUENT—Phosphorus; the whole combined in the form of a Syrup, with a **SLIGHTLY ALKALINE REACTION.**

IT DIFFERS IN ITS EFFECTS FROM ALL ANALOGOUS PREPARATIONS; and it possesses the important properties of being pleasant to the taste, easily borne by the stomach, and harmless under prolonged use.

IT HAS GAINED A WIDE REPUTATION, particularly in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other Affections of the Respiratory Organs. It has also been employed with much success in various Nervous and Debilitating Diseases.

ITS CURATIVE POWER is largely attributable to its stimulant, tonic, and nutritive properties, by means of which the energy of the system is recruited.

ITS ACTION IS PROMPT; it stimulates the appetite and the digestion; it promotes assimilation; and it enters directly into the circulation with the food products.

The prescribed dose produces a feeling of buoyancy, and removes depression and melancholy; *hence the preparation is of great value in the treatment of Mental and Nervous Affections.* From the fact also that it exerts a double tonic influence, and induces a healthy flow of the secretions, its use is indicated in a wide range of diseases.

DUNCAN'S CHLOROFORM.

ALTERATION OF LABEL.

Below we append facsimiles of the labels now in use.

CHLOROFORM **DUNCAN'S PURE S.G. 1·490.** PREPARED ENTIRELY FROM BRITISH ETHYLIC ALCOHOL BY DUNCAN, FLOCKHART & Co., EDINBURGH & LONDON.	*NOTE.*—This, which is prepared entirely from British Ethylic Alcohol, is the only CHLOROFORM which we supply as *Duncan's Pure*, S.G. 1490. To be kept Cool, and not exposed to a Strong Light. POISON.	THIS LABEL IS PRINTED IN BLACK INK.
CHLOROFORM **DUNCAN'S METHYLATED S.G. 1·490.** PREPARED ENTIRELY FROM METHYLATED SPIRIT BY DUNCAN, FLOCKHART & Co., EDINBURGH & LONDON.	*NOTE.*—This CHLOROFORM answers the tests of the British Pharmacopœia, but it must *not be confounded with* "DUNCAN'S PURE," which is prepared entirely from Ethylic Alcohol. To be kept Cool, and not exposed to a Strong Light. POISON.	THIS LABEL IS PRINTED IN BLACK INK ON ORANGE PAPER.

DUNCAN, FLOCKHART, & CO.,

Manufacturing Chemists, EDINBURGH.

HIGH-CLASS PHARMACY.

SAVARESSE'S CAPSULES.

NOT MADE OF GELATINE.

Being made of MEMBRANE, they are free from the objections to all Gelatine Capsules.

SANDAL WOOD OIL, 4/6.

COPAIBA, 2/6.

SAVARESSE'S Capsules of ORGANIC MEMBRANE do not dissolve in the stomach (avoiding nausea and irritation), but generally in the intestines.

The late Mr. W. ACTON, F.R.C.S. (p. 96, "Urinary Diseases"), recommended them.

SAVAR'S Cubeb Cigarettes.

For Asthma, Chronic Cough, Influenza, and Hay Fever, Cubebs smoked so far as to get the effect of the resins down the throat are always worth a trial. 1/- and 2/6 boxes.

MONTSERRAT LIME-FRUIT JUICE

True Lime Fruit Juice is a very useful acid drink, when diluted. The best is from the Consignee's Estate in Montserrat, W.I., of which over 100,000 gallons annually come over to the Sole Consignees. It is pure, reliable, pleasant, and a genuine anti-scorbutic. Imperial Pints and Quarts.

PRESCRIBE

CASCĀRA-HAWLEY

FOR

CONSTIPATION.

A reliable Laxative is often wanted (especially for Ladies and Children). Nothing can be better than the B.P. Fl. Extract of Cascara Sagrada, rendered tasteless by an envelope of gelatine, equal to ½ drachm of fl. extract. In Pregnancy and Habitual Constipation invaluable. 1/1½ and 4/6 boxes.

SAVAR'S COCA WINE

WHAT COCA WINE SHALL WE ORDER?

SAVAR'S, brought out in 1875, is standardised to contain ¼ grain pure Cocaine in each fl. oz., and 2 fl. drachms is a dose. Many Coca Wines *cannot* be sold by chemists without a wine licence, because so weak in Cocaine—SAVAR'S *can*. Physicians know exactly what they are doing in ordering this stimulating tonic.

Bottles 4/- and 7/-.

EVANS' FLUID EXTRACTS.

The Perfection of Pharmacy. Made with special menstrua, they represent weight for weight of the crude drug, of which they contain the *whole* of the medicinal properties. Always reliable; keep well. Tinctures and infusions can be immediately prepared from them, one minim representing one grain of the drug. Full List, with Doses, &c., on application.

Lescher's Recent Materia Medica, 4th Edition, 500 Drugs, with Doses, Formulæ, &c., 2/6.

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic,** we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialties—

ELBERFELD FARBEN FABRIKEN CO., Ld., 19, St. Dunstan's Hill, LONDON, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

For the Treatment of Tuberculosis, Chronic Intestinal Diseases, Enteric Fever, &c.

While possessing the purely curative action of beechwood creosote and guaiacol, Creosotal and Guaiacol Carbonate have absolutely no caustic effects. The tolerance displayed to these two carbonates depends on:

1. The absence of caustic and poisonous properties.
2. The absence of the intensely nauseous creosote taste and odour.
3. The fact that resorption takes place, not in the stomach, but in the intestines.

Guaiacol Carbonate and Creosotal act *continuously and mildly* on the digestive tract and the entire organism. This continuous absorption is a necessary condition for their therapeutic effect. Disassociation takes place slowly in the intestines; and, unlike other antiseptics, *the Carbonates are distributed over the whole duodenum, jejunum, and ileum.* While creosote and liquid guaiacol injure the digestive tract by causing chronic inflammation of its mucous membrane, Creosote Carbonate and Guaiacol Carbonate tone it up and stimulate it.

We beg to draw attention to Von Heyden's Preparations:—

ACTOL (Crede's Lactate of Silver.)
ANTISEPTIC CREDE (Citrate of Silver).
APOLYSIN.
GUAIACOL, crist and liquid.
ORPHOL (Betanaphtol-Bismuth.)
XEROFORM (Tribromphenol-Bismuth.)
SOLVEOL.
UNGUENTUM CREDE (Ointment of soluble metallic silver).

FREE SAMPLES and LITERATURE are sent on application to

NEURALGIA.

THE one great characteristic of all varieties of neuralgia is debility of the nervous system, and whatever tends to produce structural or functional enfeeblements of the nerves induces neuralgia, hence all the causes inducing loss of nerve power may be cited as causes of neuralgia. This affection, when not directly the result of some physical cause interfering with the integrity of the nerve system in which the pain is situated, is invariably due to loss of nerve power. Its very existence is evidence of deficient energy. The remote factor may be malaria, syphilis, rheumatism, gout, or any other cause capable of devitalizing the organism, and as a consequence that of the nerves also. Our remedial measures should therefore be directed principally to improving the nutrition of the nervous system generally, and to the removal of any constitutional taint that may be present. The first indication is filled by CELERINA and a generous diet. In facial neuralgia and brow ache it should be administered in connection with quinine, or other tonic remedy, and if malarial influence be suspected, full doses of some reliable anti-malarial remedy should be given. The CELERINA treatment is also applicable to sciatic and spinal neuralgias. Neuralgia in men is frequently an expression of loss of nerve power, and the direct consequence of dissipation and excesses of various kinds, but over-work and intense intellectual exertion will also produce it. Where the pain is located is of little moment, the treatment should be general. In these cases CELERINA seldom fails to give relief. Women suffer more frequently and more intensely from neuralgia than men. They are liable to be affected by all the causes which induces it in men, besides the derangements in health associated with menstruation—menorrhea especially. Hyperfecundation (rapid child-bearing), frequent miscarriage, hemorrhage, prolonged lactation and changes occurring at the climacteric period of life, all tend to induce a neuralgic condition of the nerves. The general treatment should be directed to the removal of the cause whenever this is possible. In these cases CELERINA, combined with ALETRIS CORDIAL will be found to exercise a magical influence.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

PROTARGOL.

A new Silver Preparation, highly efficacious in the treatment of Gonorrhœa, and most strongly recommended as an Antiseptic Wound Healer. PROTARGOL contains 8 per cent. of silver, and is easily soluble in cold or warm water, is non-irritating, and possesses a better penetrating effect on the tissues than any other known silver preparation. PROTARGOL is a chemical compound of silver and a protein substance. Its solution is not precipitated by albumen, chloride of sodium, or diluted hydrochloric acid.

Dr. BENARIO, of Frankfort, declares that PROTARGOL possesses high bactericidal properties, and is therefore excellent for the treatment of Wounds. Professor NEISSER, of Breslau, states his opinion that PROTARGOL is the best, the safest, and the quickest remedy he has yet employed in the treatment of Gonorrhœa. An eminent surgeon, in "THE PRACTITIONER" for March, confirms, so far as his experiences go, the favourable opinion expressed by NEISSER, especially with reference to its powerful anti-bactericidal properties. The usual strength of the solution for injection is ¼ to 2 per cent.

SAMPLES and LITERATURE can be had on application to the Wholesale Depôts for all Bayer's Drug Specialities—

ST. RAPHAËL QUINQUINA TONIC WINE.

HAS A DAILY SALE IN FRANCE OF OVER 15,000 LITRES.

A GLASS should be taken BEFORE or DURING MEALS.

ST. RAPHAËL QUINQUINA is a TONIC WINE of the greatest value and of delicious flavour. For Loss of Appetite, Anæmic Conditions, and Nervous Depression it is the most wonderful tonic ever brought before the public. In Paris it has by far the largest sale of any tonic wine, and is in great demand as an appetiser. For ordinary beverage purposes, mixed with mineral water, it is most refreshing, agreeable and stimulating.

The attention of the Medical Profession is invited with every confidence and Samples forwarded free on application.

Proprietors: **SOCIÉTÉ ANONYME DU ST. RAPHAËL QUINQUINA, PARIS.**

Price 39s. per Dozen, carriage paid,
In Cases containing 12 Bottles (equal to 2 Gallons).

HOOKER'S MILK WINE

Of extreme utility in cases of—

DYSPEPSIA, ANÆMIA, DEBILITY, TUBERCULOSIS, PHTHISIS, INSOMNIA, HEART WEAKNESS, TYPHOID & OTHER FEVERS, ALL WASTING DISEASES, MENTAL & PHYSICAL OVERWORK, LOSS OF APPETITE, &c., &c.

"VILNAC" Registered Trade Mark. (PATENTED)

A PEPTONIZED product of milk containing all the constituents of the original milk (except fat) in a completely digested form. It is of great medical value for use in the sick-room—for convalescents—for those suffering from dyspepsia, insomnia, nervous disorders, &c. Its value consists in the fact that the whole of the casein or curd of the milk is present in the Wine in the form of peptones, which are capable of being absorbed into the system **without digestive effort.** Whilst possessing all the valuable properties of a highly peptonized Milk, it takes the form of a sound and palatable Wine, of great use in all febrile disorders and cases of acute illness where milk, or milk and a stimulant, is essential and often difficult to administer. It is, in fact, a **powerful food stimulant** and tonic, and may be used successfully both in illness and convalescence. It is a most useful **appetizer** and aid to digestion under any circumstances, especially for the weak and aged. Many valuable testimonials have already been obtained from medical men and others who have tested and used the Wine.

A PHYSICIAN IN LARGE PRACTICE CERTIFIES:—"HOOKER'S MILK WINE is a valuable addition to the dietary of the sick room, and I have found it a powerful restorative and stimulant, not only in severe illness, but also in cases of nervous exhaustion induced by overwork, study, and other causes. It has also been used with marked and surprising success where no other food could be taken, and I have been struck with its value as an appetizer when taken shortly before a meal."

The MILK WINE is sold in wine quarts and pints. Prices, respectively, 4/6 and 2/6 per bottle, and may be obtained through any Chemist, or from the Manufacturers:—

THE MILK WINE CO., Ltd., 9, Arundel St., Strand, London, W.C.

FREE SAMPLES TO MEDICAL PRACTITIONERS ONLY will be sent on application. Included with each sample is a small bottle of Tannic Acid in solution. A simple experiment will then immediately demonstrate the Milk Peptones present in the Wine.

An Address
ON
SOME CLINICAL EXPERIENCES.

Delivered before the Torquay Medical Society on June 15th, 1898,

BY PAUL SWAIN, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

GENTLEMEN,—As you have done me the honour to ask me to give an address to your society I propose to make some remarks on cases which have occurred in my practice; and I shall first call your attention to some conditions connected with the stomach requiring surgical interference. I cannot refrain from recalling to your recollection a very remarkable gastrotomy which I reported in full in THE LANCET of June 22nd, 1895. The case was that of a young woman, aged twenty years, from whose stomach I removed by gastrotomy a mass of hair weighing 5 lb. 3 oz. This was the third case recorded, the mass of hair removed exceeding in weight the other two, which respectively weighed the one 2 lb. and the other 10 oz. The curious fact about the condition of this patient antecedent to the operation was that during the time she was in hospital she exhibited no symptoms of stomach disorder and was able to eat and digest the ordinary hospital diet. The incision made in the stomach was 6 in. in length, which was afterwards closed with twenty-six Lembert's sutures of fine silk. I heard of her a short time ago. She went to America, married, and has a child. The operation of gastrotomy is not often called for. It is principally required for the removal of foreign bodies. It is very generally believed that most bodies which can pass into the stomach by the cardiac orifice will pass out again through the pylorus. Those which are retained are generally long bodies, such as knives, forks, &c. But it is hardly to be expected that the hoop of a barrel 15 in. long would pass out of the stomach. The only wonder is, like the fly in amber, how it got there. Such a case is reported by Fournier. Then, again, a number of small bodies may become agglutinated together and remain in the stomach. Mr. Mayo Robson removed from the stomach of a girl, aged twelve years, the following digestible items: 42 cast-iron garden nails, 1⅛ in. long; 93 brass and tin tacks from ½ to 1 in. long; 12 large nails, some brass-headed; 3 collar studs; 1 safety pin; and 1 sewing needle.

It is quite possible to reach foreign bodies impacted in the lower portion of the œsophagus through an opening made in the stomach as near the cardiac end and as high as possible. But the difficulties in removing them are greater than might be supposed and Mr. Jacobson records a case in which he failed to dislodge a toothplate even after he had opened the stomach sufficiently to introduce his whole hand. On the other hand, Professor Richardson[1] of Harvard University removed a tooth-plate, which had been impacted eleven months, from the œsophagus through the stomach. I have twice performed Loreta's operation for dilatation of the pylorus through a stomach incision. I regret to say they were both fatal. In the first case the pylorus was reduced to the size of a goose-quill and it was found with considerable difficulty. The little finger was at first forced through the constriction and it was then dilated up so as easily to admit the fore and middle fingers. The patient lived for five days and then died from the result of constant vomiting. At the post-mortem examination the stomach wound was found firmly united. In the second case the pylorus was not so constricted and was dilated up to four fingers. The patient died from collapse four hours after the operation. At the post-mortem examination the duodenum was found to be very thin and at its junction with the pylorus at the back the mucous and muscular coat was torn through so that blood and gas were extravasated into the subperitoneal tissue. She had also a very extraordinary hour-glass constriction of the stomach caused by the cicatrices of old ulceration. The constricted portion formed a tube 2 in. long and was at first supposed to be the œsophagus. Both these patients were in a very weak state and the fatal results were not surprising. This reference to Loreta's operation would not be complete unless I called your attention to another procedure which, although I have never had an opportunity, I should certainly have recourse to in any case of pyloric stenosis which required operation. I refer to the operation of pyloroplasty. Mr. Pearce Gould[2] has described this operation and I give you a condensation of his description. The abdomen being opened by a median incision an incision one inch long was made into the stomach close to the pylorus and in the long axis of the stomach. The little finger was then inserted and the pyloric orifice found contracted to the size of a crowquill. The incision was then prolonged into the duodenum until it measured rather over two inches. The opening was then widely stretched with blunt hooks and sewn up transversely. The mortality following this operation is said to be about 25 per cent., whilst that attending on Loreta's operation is at least 40 per cent. Non-malignant strictures of the lower end of the œsophagus may also be treated through a gastrotomy. Two such cases are recorded, in both of which the strictures were dilated with instruments, the results being most satisfactory.

I now pass on to another operation on the stomach—gastrostomy. Up to quite recently I have been in the habit of performing this operation by drawing up a portion of the stomach and attaching it to the parietes by a number of fine silk sutures, so that a portion of the stomach of about the size of a shilling is presented in the wound. Then subsequently, three or four days after, a very small opening was made with a sharp tenotomy knife and a catheter introduced for feeding purposes. In my own experience and in the results which I have seen in the practice of others I have not been impressed with the success of this procedure. When, therefore, a short time ago I was called upon to perform gastrostomy I adopted another method—that of Albert's. I have twice performed this operation and have seen it done twice by other surgeons and the results in all four cases have been so satisfactory that I shall not hesitate to adopt this method in the future. I will now describe the operation in detail. An incision about four inches long is made parallel with the left costal cartilages and about one inch to their inner side. The peritoneum is opened to the same extent. The stomach is then sought for and a central portion of the anterior wall seized and drawn out of the wound for some three or four inches; a stout silk is passed through the apex of the cone thus formed, including the peritoneal and muscular coats only. This silk is for holding purposes. The peritoneal coat of the stomach is then attached to the parietal peritoneum by a continuous suture of fine silk. There is some little difficulty at this step of the operation. The stomach is so contracted that the upper and lower borders approximate, and it is difficult to pass the needle without wounding the large plexus of vessels passing from the omentum on to the stomach above and below. When, however, the suturing is completed the peritoneal cavity is effectually closed. The next step in the operation is to raise a portion of skin from the outer edge of the wound for about two inches over the ribs. This can easily be done by separating the cellular tissue with the finger. At the upper end of this wound a counter opening is made. The silk attached to the stomach is passed up through this opening and the apex of the stomach-cone drawn a little way into the counter opening. It is then attached to the edge of the wound by four silk sutures. The parietal wound is closed with silkworm gut sutures. Before the patient leaves the table the stomach is opened, a catheter is introduced and four ounces of milk with some brandy are poured by a funnel and tube into the stomach. The first case in which I performed this operation was in a lady, aged seventy-three years. She was somewhat emaciated, but had only quite lately been unable to swallow a sufficient amount to sustain her and had been for about a week kept going by nutrient enemata. The operation was performed on Jan. 18th at a private home. She had no bad symptom and lived in great comfort until May 21st. She then died from extension of the disease to the trachea, which had been gradually encroached on. The second case was in a lady, aged sixty-six years. I operated on her also at a private home on March 18th. Unlike the first case, she was very sick for some hours after the operation, but on the second day feeding by the stomach was resumed. Since

Digitized by Google

then she has gone on quite well. I have seen this patient to-day; she is perfectly comfortable, has gained flesh, and is able to go out and walk about. She takes about two quarts of fluid nourishment with Benger, sago, &c. In both these cases we may feel satisfied that the operation has been most beneficial and has saved the patients from one of the most distressing terminations to life—death by slow starvation. This operation we have been considering is called for to alleviate those distressing conditions which ensue upon the obstruction of the entrance of food into the stomach. But there are other conditions equally painful which prevent the exit of the contents of the stomach through the pyloric orifice. I allude to malignant growths either in the pylorus itself or external to it but occluding the passage by pressure. I shall not speak of the excision of these growths by pylorectomy because I wish to limit my observations as much as possible to my own personal experience and I have never performed this operation. But there is another method of relief, much less severe than pylorectomy, which in well selected cases is calculated to prolong life and ease suffering. I allude to gastro-jejunostomy or lateral approximation between the wall of the stomach and the jejunum. The following is the description of this operation. A median incision not less that 3 in. long between the ensiform cartilage and the umbilicus is made and the peritoneum being opened the jejunum is sought for. It is rather difficult to find, and portions of small intestine have been attached to the stomach not far from the ileo-cæcal valve—a very fatal mistake to make. The pancreas and the transverse meso-colon are the two landmarks. The great omentum having been either turned up or pushed well over to the left side the hand is passed down to the spinal column and sliding over the pancreas it comes on the jejunum just below it. The characteristic of this jejunal commencement is that it is the only portion of the small intestine which is fixed. If, then, on drawing on the bit of bowel held by the fingers you find it fixed you may be sure that you have jejunum. A point a foot further on should be selected for approximation, so that there shall be no drag upon the loop. The question as to whether the anterior or posterior wall of the stomach should be selected is a moot point. The anterior wall is the more easy, but it involves a greater drag on the jejunum, which has to be carried over the transverse colon, and it does not afford so good an exit for the contents of the stomach. On the other hand, it has been asserted that the intestine is more likely to kink if attached to the posterior surface. Besides which the operation is more complex, as it involves the displacement of the stomach and the perforation of the gastro-colic omentum. In the two cases in which I have performed this operation I selected the posterior surface of the stomach and in neither case had I any reason to regret the selection.

The next point to be considered is the method of union, whether by stitching, by one of the various bobbins, or by Murphy's button. There is no doubt that, as far as rapidity goes, the latter method is the best, as I believe it to be in all cases of lateral approximation. I used the button in both cases and found it satisfactory. In one case the patient made a good recovery, passing the button on the eighteenth day. She was immediately relieved from all sickness and lived in comparative comfort for eight months. The second case was equally satisfactory as far as the immediate results went. But on the fifth day, as Rider Haggard says, "a curious thing happened." She was attacked by severe and constant stercoraceous vomiting and died in a few hours. At the post-mortem examination we found it was not a case of malignant disease of the pylorus at all, but an epithelioma of the hepatic flexure of the colon matting all the parts together and occluding the pyloric orifice by pressure. Perforation had taken place into the stomach—hence the stercoraceous vomiting.

We now leave the surgery of the stomach and pass on to consider some of those conditions of intestinal obstruction requiring operative measures. It is obvious that I cannot within the compass of this address range over the whole question, very interesting as it is to all of us, of intestinal obstruction. I propose, therefore, to select some typical cases for your consideration. The first case I refer to is particularly interesting to myself, for it was the first occasion in which I used Murphy's button. I have reason to think it was one of the first cases in which this method had been adapted in England. A boy, aged nine years, some eighteen months before had received a severe blow on the abdomen which set up a general peritonitis. He recovered, but soon after began to get recurrent attacks of obstruction accompanied by pain, distension, and sickness. These attacks at last became so frequent that I advised an abdominal section. He was removed to a private home. As I expected I found a portion of small intestine tightly constricted by the products of inflammation. I removed about 8 in. of bowel, uniting the cut edges with Murphy's button. The boy made a most satisfactory recovery, passing the button on the ninth day. From that time to this he has been perfectly well. Quite recently, on Dec. 31st, 1897, I operated on a man with a very similar condition arising from a different cause. Some months before he had been operated on in the country for a right inguinal hernia. As far as the operation went all was well, but three weeks after he began to develop symptoms of chronic obstruction. We came to the conclusion that in all probability the portion of bowel involved in the hernia had become matted together by bands and that this was the source of his symptoms. I opened his abdomen and found this to be the case. A long portion of bowel was removed, and a Murphy's button was inserted, which was not passed for three weeks. The man made a good recovery and I have just heard from his medical man that he is in perfect health and working as a navvy. The anxious part about this case is that when the intestine removed was cut open a large granular growth was found on the mucous surface. There were also some enlarged glands in the mesentery. It looked very like a malignant growth and was afterwards pronounced by the pathologist to be an epithelioma. The after history of the case does not bear out that opinion.

A word as to the merits of Murphy's button. One is always inclined to speak well of the bridge that carries you over and certainly I have had sufficient success with this method to enable me to express a high opinion of its utility. I have never had a case in which the button has been retained except one. That was a case in which I attached a huge bile cyst to the duodenum by the button. It is now some four years ago; the button has never appeared, but the girl is none the worse for its retention. As I have before said, for lateral approximation I believe it is unequalled; but there is one difficulty attending its use in end-to-end union. Where you have a stricture of the bowel it must needs be that the portion of intestine above the stricture is largely distended, whilst that below is contracted. The result is that the dilated end of the bowel is with difficulty included in the button. I am inclined to think that Allingham's or Mayo Robson's decalcified bobbin are better adapted for this purpose, although as a rule it cannot be so rapidly applied, and saving of time in these cases is of paramount importance.

My next clinical experience is one of very great interest, partly from its rarity and also from its very successful termination. In October of last year I was asked to see a man in the country in conjunction with Mr. Lucy and Dr. T. E. Smyth of Tavistock. He was fifty years of age. For two years he had suffered from constipation. For two months he had had tenesmus with passage of blood and mucus. This became acute and for a week no fæcal matter was passed. On examination under chloroform the rectum was found to be ballooned and occupied by a rounded tumour, the posterior part was hard and nodulated, the anterior portion was soft and velvety, the lumen of the bowel being here detected. This tumour could be reduced by forcible injections, but immediately recurred. The diagnosis was intussusception of the sigmoid flexure into the rectum caused by the presence of a malignant growth. I performed the following operation. The patient was placed in the lithotomy position and the sphincter was widely dilated. The intussusception was then seized by two strong vulsella and drawn down through the anal aperture until about 6 in. protruded. The forefinger of the left hand was then passed up the bowel well beyond the growth, the thumb steadying the gut outside; care was taken to ascertain that no small intestine had slipped down between the layers of the gut. With a curved needle a fine silk ligature was passed parallel to the longitudinal axis of the gut through all the coats of the intussusception and fully one inch above the growth. When the point of the needle was felt on the forefinger it was turned outwards and brought out about a quarter of an inch below the point of entrance and the ligature tied. This process was repeated until the whole circumference had been ligatured with fifteen sutures. As the sutures were applied the bowel was gradually opened and

Digitized by Google

divided about half an inch below the ligatures. One of the great difficulties of the operation was the protrusion of the appendices epiploicæ, which were with difficulty replaced and retained during the tying of the sutures. In fact, after all the sutures had been placed it was needful to apply many superficial ones in order to cover in these protruding bodies. When the entire mass was removed an attempt was made to reduce the stump, but this could not be accomplished. However, the next day the bowels were opened spontaneously with the passage of large quantities of scybala, but no blood and without tenesmus. The rectum was examined and no trace of the intussusception could be discovered. From that time the patient made an uninterrupted recovery and is now in perfect health. The growth was reported to be columnar epithelioma. This is the seventh recorded case of intussusception caused by malignant growth operated on. Three were fatal.

Remarks
ON
THE TREATMENT OF FRACTURED BONES BY OPERATION.

Delivered at University College Hospital,

BY ARTHUR E. BARKER, F.R.C.S. ENG. & IREL.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE; SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The question as to the propriety of treating fractures by surgical operations by wiring is one which at the present time is engaging a good deal of attention. As yet the majority of surgeons appear to be agreed that for most ordinary fractures other and simpler mechanical modes of treatment are quite adequate and involve less risk, and with this view I entirely agree. There are, however, a considerable number of fractures which proverbially give but indifferent results if treated by mechanical appliances, and to these surgeons are beginning to apply operative treatment in ever increasing numbers. To this class belong fractures of the patella and of the olecranon, whether recent or old, and fractures of the long bones of the leg or arm in which union is long delayed or totally absent. Hitherto the great bugbear in the operative treatment of such fractures has been the risk to limb or life involved in the operation. The nature of these risks we all know and in the past they have very properly checked and limited operative undertakings. But how far this ought to be the case now with our greatly improved technique is a matter which appears to me to be open to discussion. With a view to clear my own impressions upon this subject I have for some time past been collecting those cases in which I have operated for fractured bones and studying the results in order to see whether the series appears to justify such interference or not. As these results will probably interest others who are speculating on the same subject I venture to publish them here. I have only to remark, in reference to them, that they include all the cases, without any exception that I am aware of, in which I have operated for injury of bones recent and old. If they have any value it lies in the fact that they form an unbroken series and have been operated on by the same surgeon, with almost identical precautions in each case against surgical accident. From the notes in the abstract which are now before me, but which are too voluminous for publication, I find that in all there are 46 cases, including some cases in which bones have been divided for various reasons and subsequently sutured, such as, for instance, where the patella or olecranon has been sawn across to explore a joint or reduce a dislocation but not including excisions. Of the latter it may be said that though their fate would materially and favourably influence the question of the justifiability of interfering extensively with bones they belong to a somewhat different category. I will only add that of all my excisions, for instance of the knee, amounting to some scores, I have lost none and only 2 have subsequently required amputation—the case of an old woman whose knee I tried to save and a young woman who came to me for amputation but whose leg I tried to save first by excision. The 46 cases alluded to arrange themselves thus: subcutaneous suture of patella for fracture, 19; suture of patella (open method), 10; suture of olecranon for fracture, 6; suture of olecranon for dislocation, 2; suture of bones of forearm (ununited fracture), 2; suture of bones of leg (ununited fracture), 4; suture of clavicle (ununited fracture), 1; suture of patella after division, 2; total, 46.

Of the first group it need only be said that all have recovered well from the operation without any accident. I have made every effort to follow these cases up to date and have seen the majority a long time after operation. The results have been excellent. In some few a little limitation of movement has remained, but the limb has been firm and as far as could be made out the union of the fragments was osseous. In none so far has the wire appeared to give any trouble. Of several I possess skiagrams. These show that though the union is bony the adjustment of the fragments to one another was not always symmetrical. This has not appeared to unfavourably influence the movements of the joints, as, indeed, could hardly be expected, as little irregularities in the patella in rheumatoid arthritis do not always do so we know. Several of the patients were absolutely restored to as good use of the injured limb as though it had not been damaged at any time. Those cases in which stiffness was noticed to any extent were past middle life and it was seen even in cases which had healed without reaction. On the whole I am very well satisfied with my subcutaneous method of suture for recent cases at any age. For fractures which have remained ununited, for months of course the open method will be required, but such cases will, I venture to think, become rarer and rarer as the simplicity and freedom from risk of the subcutaneous method is more fully recognised.

Of old fractures of the patella there are 10 cases and of these 8 healed by first intention without any suppuration. Cases 2 and 7 suppurated but not very seriously. The first was one of my earlier cases treated long ago and the suppuration was in the peri-articular structures. I saw the patient years later with an excellent moveable knee and removed the knot of wire which was giving him some trouble. Case 7 was one of comminuted fracture of the patella, almost compound, with loose fragments which had to be removed. Those which remained were surrounded with a "purse-string" suture and thus drawn together. Some swelling followed and effusion into the tissues above the knee, but though I made incisions only serum escaped. The main cavity of the joint appeared to be quiet all the time, though the suture wound opened and the wire had to be removed in part. I have put this down as one of suppuration as there certainly appeared to be some, and the wound yielded pus, though not to a large extent. I have lately seen the patient, who is well satisfied with the result. There is much stiffness in the knee, though I think this will pass off to a great extent in time. One of the last cases operated on was particularly interesting; it was one of transverse fracture by very slight muscular action. But the joint was enormously swollen and looked as if about to suppurate. I opened the joint by a curved incision with the convexity upwards—a method I have already published—and found a great deal of broken-down blood-clot, almost purulent, as one of my colleagues remarked. This was removed and the bone fragments brought together with one silver wire. The wound healed absolutely by first intention and the patient left the hospital. Before he went he was discovered to have ataxic symptoms. Two months later he was admitted to the medical wards as a case of Charcot's knee, the joint having become greatly distended. As there appeared to be pus in it it was opened by a colleague during my absence and much broken down purulent material was evacuated. It was then found that the wire had worked through the lower fragment and was loose. It was removed and the joint was drained. The man soon left the hospital healed but with all the signs of ataxy and has not since been seen. Had the condition which probably favoured the fracture been recognised at the outset I should not have operated. But the man was young and the symptoms were not well marked at first. In all the 8 cases where there was no trace of inflammation after the operation the results were admirable and in the other 2 the state of the patients or their joints did not appear to be critical at any time.

Six recent fractures of the olecranon were wired and with the exception of one which was compound

Digitized by Google

and comminuted the results as to movement were admirable. All healed *per primam*, even the compound case, but here there remained great stiffness. The woman was fifty-three years of age and when the adhesions were broken down under an anæsthetic about a month after discharge from hospital the line of union in the fragments gave way in spite of the "purse string" silk suture. In the other cases the results were almost or absolutely perfect. And I have recently seen a blacksmith's hammerman whose broken olecranon I wired two and a half years ago with as strong and moveable an arm as if it had never been broken. The method employed for some years has been to make an oval flap, drill the fragments transversely, and use wire, making the knob on the outside. In only one case so far has the wire given trouble. It irritated the skin and had to be removed. In 2 cases I divided the olecranon as a preliminary to reducing old dislocations of the elbow. In one, a boy aged twelve years, though firm union resulted there was considerable stiffness of the joint when he left hospital. He has not been seen since. In another, a woman aged fifty-six years, whose dislocation dated from four months back, I divided the olecranon, reduced the dislocation, and primary union resulted. When last heard of the result bade fair to be perfect. In 2 cases the radius was cut down upon and wired for old ununited fracture. The first I have not seen since the operation; the last, a middle-aged woman, recovered with primary union and with good use of her arm. The clavicle united perfectly under one dressing and all the symptoms were relieved.[1]

In 2 cases I divided the patella for access to the joint and wired at once. The union was primary in both without reaction and the patients left for the colonies, much relieved in 1 case; the other was a private case and was quite relieved.

Of the 4 cases in which the bones of the leg were wired for ununited fracture primary union took place in all and the functional result was perfect in 3. But in the first union had not taken place in the bones when last seen and the patient cannot be traced.

These results appear to me to be encouraging, especially as they were achieved in an old hospital now happily being rapidly rebuilt. With care and experience the result ought to be better in the future, but as far as they go they appear to justify the belief that such operations if done with extreme care do not involve such risk as to forbid them.

VACCINATION: WITH SPECIAL REFERENCE TO PROSPECTIVE LEGISLATION.[2]

BY FRANCIS T. BOND, B.A., M.D. LOND., F.R.S. EDIN.,
HONORARY SECRETARY TO THE JENNER SOCIETY.

As the precise title of this paper has not been selected by myself, but is one on which I have been asked to open a discussion, I feel it necessary to give it a certain latitude of interpretation. By the term "prospective" I propose to understand not simply the legislation which is now imminent as the result of the consideration of the Vaccination Bill by Parliament, but such provisions as it has been found impossible to get incorporated into the Bill and as it is to be hoped may be placed on the statute-book at no very distant period, unless this country is to lag behind most others in the march of sanitary progress.

The vaccinist position. — It is superfluous in such an assembly as this to assume that we are all convinced that vaccination is in some degree a protection against small-pox. I have no doubt also that the great majority of us are thoroughly convinced that when properly performed it is free from serious risk and that it is nearly, if not quite, as effective a protection against small-pox as an attack of that disease itself is. I may probably go still further and may assume that there are few, if any, now present who would undertake to maintain that apart from the absolute separation of the infected person from all who are likely to take the disease—an almost impracticable condition—there are any other means of protection against small-pox which are approximately comparable with vaccination. It goes without saying that we all know very well, what is so generally ignored on one side of the controversy on this subject, that the term "vaccinated," unlike that of "unvaccinated," has no meaning which can for purposes of comparison be definitely estimated and that in using it for controversial purposes we labour under the disadvantages which inevitably attach to the employment of ambiguous terms.

The medical vaccinist as a critic.—It may be well also to refer at the outset to an objection which may be taken to the discussion by a purely professional meeting such as this of a question in the decision of which many of those present may be said to be personally interested. There are two answers to this objection, either of which is of itself sufficient. The first is that however much those who are engaged in the practice of vaccination may be assumed to be interested in the maintenance of it—and for my part I do not admit that the pecuniary interests of the medical profession as a body lie in this direction—this does not exclude them from the right—nay, does not absolve them from the duty—of discussing a matter which affects them in their individual capacity as citizens as much as it does other people. It may give a bias to their opinions, but that must be estimated by those who care to consider them. The second answer is that assuming, as is so often done, that medical men are prejudiced in favour of vaccination and therefore are not impartial judges of what is right and expedient in this matter, their opinions are entitled to the more respect if it should turn out that they are less enthusiastic in favour of the coercive promotion of vaccination than they are often assumed to be—less so, in fact, than many non-medical enthusiasts have shown themselves to be. In illustration of this view of the matter it may be pointed out that an unsuccessful proposal to absolve determined objectors to the compulsory vaccination of their children in infancy was made by a leading member of the medical profession on one side of the House of Commons in Grand Committee on the Vaccination Bill, whilst a more successful effort in the same direction at a later stage of childhood was made by an equally distinguished member of the profession on the Ministerial side of the House. This is a fair answer to the charge so often made by anti-vaccinationist controversialists that in maintaining compulsion Parliament is led by the nose by the medical men.

Legislation as it affects the individual and community.—The legislative aspect of the vaccination question is of two kinds: as it affects the individual and as regards the community of which he is a unit. So far as the ethical basis of legislation is concerned it must be assumed that whatever may be our views of individual rights in matters of *opinion*, there is only one principle upon which the maintenance of society can be based and that is that the right of the individual in regard to *action* must be subordinate to the opinion of the majority. But whilst strictly insisting on the imperative character of this principle as a general safeguard of society we must fully recognise the right of protest on the part of the individual to any legislation of which he does not approve and also that in all cases in which the volume of such protest becomes considerable the correlative question of the expediency of modifying the law against which it may be directed must engage the attention of prudent legislators. So far as the individual is concerned it must be frankly admitted that the aphorism, *de minimis non curat lex*, however unwise it may appear in conception and however harshly it may often operate in practice, is as unavoidable in vaccination as in all other matters of opinion which have to be embodied in a legal form. It is only when individuals can, from the force of their convictions or from the acuteness of their sufferings, succeed in associating their efforts so as to disturb the peace of the community or to impede the operation of the law that they can expect to obtain a hearing for their grievances, whether real or only sentimental. This may be considered as a somewhat cynical view of the matter, but it can hardly be disputed that it represents the real state of public opinion. It is obvious that this consideration applies in a still higher degree to the case of recalcitrant communities than it does to that of objecting individuals, since the difficulty of enforcing the law becomes proportionately greater as the number and solidarity of the protestants increases. Nor must we forget that in matters of opinion, as in pathology, infection often plays a very

Digitized by Google

important part, and if not judiciously treated is apt to spread with unexpected rapidity and to become unmanageable. That we have approached within appreciable distance of this state of things in regard to vaccination in this country can hardly be denied by any one who has an adequate knowledge of the real state of affairs. The unfortunate interregnum in vaccination administration necessitated by the prolonged inquiry of the Vaccination Commission has led to a crisis which can only be described as a state of administrative chaos.

How does the Vaccination Bill meet the crisis?—Looked at from this point of view there are two questions which, both as citizens and as medical men, we are called on to discuss. The first is, how far does the Vaccination Bill meet the agitation against the Vaccination Acts which has been steadily increasing in volume since those Acts, and especially that of 1867, were passed? The second is, assuming, as the Royal Commissioners unanimously recommended, that vaccination is to be promoted by the State, so far, at any rate, as the maintenance of the existing machinery is concerned, what provisions are necessary in order to carry out that object effectively?

The agitation against vaccination.—That the agitation against vaccination which commenced about thirty years ago has been since then steadily growing is a fact much less generally appreciated than it should be. The refusal by boards of guardians to enforce the compulsory sections of the Act of 1867, which was for some years unheard of, has during the last decade become a familiar occurrence. This may no doubt in some degree be attributed to the excuse which the protracted inquiry by the Royal Commission has offered to many boards who, though perhaps prepared to carry out the law as it may be modified by Parliament as the result of this inquiry, have been glad to avail themselves of this pretext for at least suspending action. Indeed, had it not been for the experience of Gloucester, followed so soon after by that of Middlesbrough, it is probable that the general dereliction of prosecutions would have been much more extensive than it has been. What has been the cause of this apparent unwillingness of vaccination authorities to carry out the law? It certainly is not attributable to any decline of confidence on the part of the medical profession in the efficacy of vaccination as a protection against small-pox when rightly and duly employed. If there were any question on this point it would be settled by the recent declaration of over 1100 medical officers of health that in their opinion vaccination is the only trustworthy protection against small-pox, both for the individual and the community. Every epidemic—nay, every isolated outbreak of small-pox—only adds fresh evidence to the huge mass which the experience of a century has accumulated. So huge, indeed, is it that only those who, like the Royal Commissioners, have had to wade through it, even with the assistance which their report affords, can form any idea of the weariness of the effort required. There is, of course, as we all know, a sufficient explanation of the enfeeblement of the law which has been thus steadily taking place.

Its causes.—It is to be found in three causes. The first of these is the natural intolerance of the ordinary Briton for compulsion in any shape, and especially for compulsion in matters which intrude within the domain of private opinion, of the relations of the family, or of the sacredness of the person. It is needless to discuss the reasonableness or the reverse of this feeling; we must accept it is as a fact. The second cause is the unquestionable occurrence of mischief which, whether rightly or wrongly attributable to vaccination, has certainly followed it. The third is the recognition of results connected with the spread of small-pox which appear at first sight, and when incorrectly represented, to be incompatible with the claims made for the protective value of vaccination. It is quite unnecessary to assume that the efforts which have been persistently made to appeal to the intolerance of control, which we all feel, and to parental sentiments, which are worthy of the highest respect, by an exaggeration or misrepresentation of the seriousness of this mischief have been actuated or even materially maintained by disingenuous motives. Bare justice demands the recognition of the fact that the great majority of those who have taken an active part in the agitation against vaccination have had more to lose than to gain in so doing, so far as their pecuniary interests are concerned. That paid advocacy has played a part in this, as it does in all prolonged agitations for the spread of new opinions, may be admitted without thereby reflecting on the good faith of those who have availed themselves of it. Paid advocacy may suggest caution in receiving the statements of the advocate, but it is in no way incompatible with their being true. We must look in a different direction for an explanation of the enthusiasm by which what we cannot but regard as the wrong-headedness of the anti-vaccination movement has been so persistently maintained. It is to be found in the tendency, largely unconscious, which we all have in matters of opinion to exaggerate everything which appears to support what we ourselves believe, to give undue weight to sentiment as opposed to reason, and to view in a false perspective the relative features of our mental landscape. It is only necessary to give the names of some of the men who have identified themselves with the anti-vaccination movement to appreciate the fact that this tendency is not confined to the illiterate or even to those who are destitute of scientific culture. The name of at least one of the protagonists of the anti-vaccination cause might be quoted to prove that it is consistent with the highest degree of mental training and originality.

The crude Bill.—How does the Vaccination Bill propose to meet this state of things? As is well known the Bill first laid before the House of Commons contained only three provisions which are material to this question. It proposed to limit prosecutions to two, or perhaps three, at the most; to compel the use of glycerinated calf lymph by public vaccinators, unless the parent or other person with whom the discretion lies prefers some other form of lymph; and to offer, and in many cases to personally present, this lymph at the home of the defaulter. It must be evident to anyone who has any acquaintance with the conditions which led to, and have so long maintained, the anti-vaccination agitation that those who are responsible for the Bill must either be singularly unacquainted with the history of this agitation or excessively sanguine as to the power of glycerinated calf lymph in dissolving it if they thought that the Bill in this form would put an end to it.

"Glymph" as a solvent of doubts.—One would almost fancy, from some statements which have been made on the subject, that we had never heard of glycerinated calf lymph, or "glymph," as it has been proposed for brevity to call it, until it was revealed to us by the Bill; whereas, as we all know, it has been in use by private vaccinators for years past. The best indication of its value as a solvent of anti-vaccinist doubts is that in Germany, where the combination of glycerine with human lymph was introduced more than twenty years ago, there is an increasingly active agitation against vaccination. And it is somewhat singular, as an illustration of the different points of view from which what may be called the controversial value of glycerinated calf lymph is regarded, that whilst in this country it has been thought sufficient to make it practically the *pièce de résistance* of our new vaccination law the official German handbook on the subject of vaccination, which deals mainly with its controversial aspects, makes absolutely no reference to it at all. The Germans have adopted this agent, as a valuable laboratory device, which enables calf lymph to be employed under the most favourable conditions at present practicable, but they do not seem to think it necessary, or perhaps even expedient, to depend on this provision alone as a means of relieving vaccination from all ground of reproach, nor to pin themselves by an Act of Parliament to the compulsory use of any single preparation, as the Bill in its original form would have tied down the Local Government Board. The German Government place their reliance in minimising the opposition to vaccination, not on glycerinated calf lymph alone, but upon a carefully devised administration by which the process of vaccination in all its stages is hedged round by precautions which we entirely ignore, as a sample of which it may be mentioned that any medical man who can be shown to have performed vaccination in such a way as to expose the subject of it to needless risk is liable to a very severe penalty. The real value of glycerinated calf lymph, of course, is—and I have no desire in any degree to minimise it—that it reduces to an incalculable zero the previously "insignificant"[3] pretext which there was for magnifying the dangers of vaccination. But reasonable people who are satisfied with the opinion of the Royal Commissioners on this point will hardly need the further assurance which the purveyor of official calf lymph will now be authorised to give, whilst it is to be feared that the unreasonable people by whom the anti-vaccination agitation is entirely carried on will be in no degree conciliated by it. Upon the great majority of defaulters, the

[3] See opinion of the Royal Commissioners in final Report.

Digitized by Google

indifferent and the indolent, it will have no appreciable effect; they will not be induced to have their children vaccinated because they believe that calf lymph is any better with glycerine than it is without it, but because they know that behind the public vaccinator, with his lancet and his glycerinated calf lymph, stands the vaccination officer with a summons. The whole influence of the first of these two officials in diminishing the number of defaulters will depend on whether the sequence of the second of them can be certainly reckoned on or not. On this point still hangs, as it has hung for many years past, the vaccination problem. The mistake of specifying "glycerinated calf lymph" in the Bill has been corrected in Committee by the addition of the words "or such other lymph as may be issued by the Local Government Board." But it may well be asked why, with this alteration, the words "glycerinated calf lymph" should be retained in the Bill at all? The public must trust the Local Government Board in this matter, and the simpler provisions of this kind are made the better, in view of the handle which a superfluous word often affords to an astute lawyer for verbal strife. Surely the words "lymph as issued by the Local Government Board" would be sufficient for the purpose.

Need for the diffusion of knowledge.—But apart from the bigoted antivaccinist on one side, whom nothing will convince, and the indolent and indifferent parent on the other, who can only be compelled to face his responsibility by the strong arm of the law, lie the great body of the British nation, who know but little about vaccination, and for the most part, also, have at the outset no prejudices either for or against it, except so far as it may be likely to entail inconvenience or discomfort upon them. They are the ready prey of the casuistry and misrepresentation which the organised machinery of the Anti-vaccination League brings to bear upon them, and they will continue to be so in default of a corresponding effort to counteract this mischief. It is a striking paradox that whilst we have for 30 years been compelling parents to have their children vaccinated we have never thought it expedient to make any official or organised effort to explain to them the grounds on which this requirement is founded. And it is a fact which is scarcely credible that if a local vaccination or sanitary authority were to incur any expenditure in diffusing literature on this subject or in any other way promoting the spread of knowledge in regard to it—except, possibly, when small-pox might be actually prevalent in the neighbourhood—those members of it who might happen to sign the cheque for so doing would render themselves liable to be surcharged by the auditor and could only obtain relief by memorialising the Local Government Board.

The amended Bill.—The Bill, when it emerged from the ordeal of consideration by Grand Committee, was distinctly improved by the process. The provision which extended the age limit within which vaccination is required from three to twelve months was altered to six months. This alteration was made chiefly on the strength of recommendations to that effect by the Council of the British Medical Association, the Society of Medical Officers of Health, and other representative bodies, and though open to some discussion is probably on the whole, a judicious alteration. The clause providing that the public vaccinator shall visit the home of the child for the purpose of vaccinating it, if requested to do so by the parent, was the most valuable one in the original Bill, as it will remove a fertile source of discontent on the part of mothers who dislike, and with some reason, taking their children to public stations. The objection to this proposal on the ground that the home of the child may for sanitary reasons be an unfit place for performing the operation was met in Committee by an amendment giving the vaccinator a discretion to withhold vaccination for this reason if he saw good to do so. As a parent is under no compulsion to invite the public vaccinator to vaccinate his child no reasonable opposition could be offered to this clause. Others which are in the same category and which were mostly added as amendments in Committee, were Clause 2, which prohibits the repeated prosecutions which have been so largely responsible for the agitation against vaccination; Clause 4, which provides that persons committed to prison for vaccination offences shall be treated as first-class misdemeanants; Clause 6, enabling the Local Government Board to make special provision for opening public vaccination stations in case of any local outbreak of small-pox; Clause 7, authorising local authorities to incur reasonable expense in distributing literature explanatory of the advantages of vaccination; and Clause 8, requiring records of cases admitted into small-pox hospitals to be kept, and making them accessible to those who may wish to consult them.

Domiciliary visitation.—The Vaccination Bill in its original form contained three other provisions besides the prescription of the use of glycerinated calf lymph. One of these, to which reference has already been made, requires the public vaccinator to vaccinate children at the homes of their parents, if called on to do so. This course, which was recommended by the Royal Commissioners, is an eminently reasonable one, and simply involves the consideration of the cost of paying for such visits. Sir Walter Foster attempted to get a schedule of vaccination fees incorporated with the Bill, but for some not very evident reason it was not accepted. A more questionable provision is that which requires the public vaccinator to offer vaccination at the home of the parent in the case of every defaulter. This arrangement, which seems very simple in theory and which was justified by a somewhat misleading analogy drawn from Scotch experience, will probably prove to involve considerable difficulties in practice. It is certainly open to two grave objections. The first is that in urban localities where the feeling against vaccination is strong it will expose the public vaccinator to treatment which is likely to make the office a very thankless one. There can be no expectation that he will convert the objecting parent, and as these visits will have to be paid for, it is only imposing useless expense on the community to require them. If it be urged that they will help to make the case stronger against the recalcitrant when he may have to be summoned before the justices, the obvious answer is that it can be made quite strong enough by giving him the offer of vaccination in another way. This may be done by requiring the vaccination officer to serve the parent with notice at the appointed time that the public vaccinator will attend at the home of the child to vaccinate such child unless he shall have received before a specified date a notice signed by the parent that he does not wish him to come. This would give the parent the opportunity of having his child vaccinated by his own medical attendant if he preferred doing so; if he did not take this course but sent a note deprecating further attention, it would save a useless visit by the public vaccinator and would serve as *primâ-facie* evidence of his irreconcilable objection. If the public vaccinator received no such notice he would be justified in going to the home of the child, and if vaccination were then refused, the refusal under such circumstances would be a fact which the justices would probably take into consideration when inflicting a penalty.

The private vaccinator ignored.—The second objection is that it may very easily create friction between the public vaccinator and his professional brethren, into the houses of whose patients he will thus be licensed to intrude. This consideration naturally leads to another, and that is that the Bill entirely ignores the fact that so large a portion of the vaccination of the country is performed by private vaccinators. The public vaccinators have complained, and with reason, that they are heavily handicapped in being required to make four insertions as a condition of being paid for their work as efficient, whilst private vaccinators are allowed to underbid them by giving certificates of what is assumed to be satisfactory vaccination on the strength of a single insertion. On the other hand, the private vaccinators have a right to complain that the Bill handicaps them by containing no provision for their being supplied with lymph bearing the Government guarantee as the public vaccinators will be. Hence, instead of a healthy rivalry being established between these two sections of the profession by which both should be encouraged to do their work with the highest degree of efficiency, an antagonism is created between them which can hardly fail to be detrimental to vaccination and consequently to the public interest. The expediency of recognising the work of private vaccinators, and of putting them on the same footing with public vaccinators, which was recommended by the Royal Commission and was pressed on the Government from a variety of representative bodies, was embodied in an amendment proposed by Sir Walter Foster and supported by Sir William Priestley and Sir Charles Cameron, but was defeated. It was opposed by Mr. Chaplin (who admitted that it would promote vaccination) for two reasons: because it would entail a heavy burden on the rates and because there was no assurance that satisfactory results could be obtained without the appointment of a

Digitized by Google

"whole army of inspectors." These objections seem capable of easy answer. The children who would be thus vaccinated would be mainly of the class who now are vaccinated at the charge of the ratepayers. All that would be done therefore would be to transfer to private vaccinators a portion of the fees now paid to the public officials. The burden on the rates would not be appreciably increased by so doing, except upon the assumption that those who are now competent to pay for vaccination would under the new regulations claim to have it done free. But this might be safely left then, as it is now, to the medical men themselves, who were prohibited by Sir Walter Foster's proposal from making any private charge if they took the administrative fee and who would scarcely accept 1*s.* 6*d.* from the rates if they could obtain more from the parent direct. As to the need for "an army of inspectors," this objection is equally susceptible of answer. The inspection of public vaccinators as now carried on by the Local Government Board can hardly be claimed to be a very effective one. A hasty inspection made once in two years, which is the amount of supervision bestowed on the bulk of public vaccinators, scarcely represents an adequate control, and it may be freely admitted that if arm-to-arm vaccination were to be maintained, any extension of this system of control to private vaccinators would be quite impracticable, except at the cost which Mr. Chaplin suggested. But he appears to have overlooked the fact that the change to glycerinated calf lymph will entirely alter the aspect of this question and that with a properly-devised form of certificate and a stiff penalty for misstatements, as proposed by Sir Walter Foster, those vaccinations by private vaccinators for which the public would be called to pay would be mainly a matter of inspection of registers, which might be well delegated to local officials.

Local option.—There is one aspect of the vaccination problem which the Bill will leave unchanged. It is this: there are unquestionably a large number of boards of guardians who at the present time are not enforcing the vaccination law. Admitting that a certain proportion of those authorities who have suspended action on the plea that they were waiting to see first what the report of the Royal Commission would be and then what Parliament would do will, when the Vaccination Bill has become law, resume the prosecution of defaulters, there will be a considerable number who are not likely to do so. In some cases these boards have ceased to take any action at all and the subject of vaccination is practically ignored by them. Others profess to consider the objections of defaulters and to deal with them on their merits. The result in this case also is much the same as in the other, for in one way or another every one who chooses to express an objection to vaccination is allowed to escape scot free. The position taken by these boards really amounts to a claim to exercise local option in a matter in regard to which Parliament has conferred no such right. The claim is founded on the assumption that boards of guardians possess a discretionary power in this matter which the law has certainly not given them. That this is the strictly legal view of the question is beyond doubt. And it is important to recognise also that this claim is only a phase of a much larger one by which some of these boards seek to emancipate themselves in all matters from any form of central control. Local option therefore in vaccination is the first serious manifestation of a revolt by local authorities, at first as boards of guardians, against the general opinion of the country as formally expressed by Parliament. As such it must be dealt with firmly, unless we wish to drift into general anarchy. Even if it cannot be checked it can be at least controlled. How is this to be done.

How to control local option.—The President of the Local Government Board has drawn attention to a fact which has escaped general observation—that Parliament has already provided in the Vaccination Act of 1874 a remedy for this state of things by investing the Board with powers in virtue of which they can directly instruct vaccination officers to carry out their duties in regard to the prosecution of defaulters where the boards of guardians, whose officers they are, refuse or neglect to take action of this kind. It is probable that many boards which had suspended prosecutions would be glad to be relieved of the disagreeable position in which they find themselves in this matter by having the responsibility of action thus taken off their shoulders by the central authority. But it is difficult to see how this can be done without a transference at the same time of all other duties in regard to vaccination from the defaulting board to some other body. The local administration of vaccination, if it is to be carried on with any energy or efficiency, must be vested in some body which is interested in so doing. Even where boards of guardians do not expressly refuse or neglect to carry out the law, they generally show little enthusiasm in regard to vaccination. And the reason is not far to seek. Vaccination is distinctly a branch of preventive sanitary action with which guardians, as such, have nothing to do. Their work is the administration of the Poor-law, and in looking after this they have quite enough to find occupation for all their energies. If, therefore, they are to be relieved of the duty of prosecuting vaccination defaulters they will not unreasonably expect to be relieved also of all other duties connected with vaccination. And it is very much in the interest of vaccination itself that they should be.

The divorce of vaccination from other sanitary work.—The fact is, and it is necessary distinctly to recognise it, that the whole of the difficulty connected with the vaccination question has largely grown out of the maintenance of boards of guardians as the vaccination authority after the creation by the Public Health Act of 1872 of sanitary authorities. Had vaccination then been placed, along with other sanitary work, in the hands of these latter bodies not only would there have been a better guarantee of its being carried out more efficiently than it has been, but there would have been much less opportunity for friction in so doing. And the reason for this is very obvious: it would in that case have become part of the work of the medical officer of health to look after it. He is officially interested in the promotion of vaccination because he is interested in the control of small-pox. It is a curious instance of the utterly illogical and fragmentary character of so much of our legislation that this divorce of vaccination from other branches of sanitary administration should ever have been perpetrated by which the medical officer of health is excluded from any connexion with one of the most important branches of preventive work. It is still more strange that although the blunder should have become increasingly evident during the quarter of a century which has elapsed since it was first made there should have been no effort to remedy it. But what is most singular of all is that at the present time, when the need for fresh legislation has been recognised by the Government to meet the official position in which vaccination has got, and notwithstanding the strong representations which have been made to them of the desirability of transferring vaccination from boards of guardians to sanitary authorities, they have not adopted this course. This would at first sight appear to be the more extraordinary because the proposal can scarcely be considered one of a contentious character, though it is only fair to admit that it would involve a good deal of legislative detail in the shape of amendment of existing Acts which, with the facilities at present available for obstructive tactics, might have been made an excuse for even greater delay than the Vaccination Bill has already experienced. It must also be admitted that so far as the majority of rural sanitary districts are concerned the variation of personality between the board of guardians and the sanitary authority is so trifling as to be unimportant. Still, with full allowance for these considerations it may be safely maintained that the Government would have been well advised to make the venture if only in the form of a provision giving the Local Government Board power to make such a transference in any case in which a board of guardians neglected or refused to carry out its duties under the Vaccination Acts. There are probably not many rural districts in which such a contingency would arise. It is in Poor-law districts which include urban populations that the transfer is most likely to be needed, and in many of these it would be as much welcomed as a relief by the board of guardians as it would be accepted without difficulty by the sanitary authority.

How to treat recalcitrant authorities.—There are no doubt towns where this would not be the case, in which the reluctance to enforce vaccination, so far as such enforcement will in future be possible, would be as great on the part of the sanitary authority as it has been on that of the board of guardians. How are such cases to be dealt with? Take Leicester, for example. The sanitary authority of Leicester professes apparently to believe that it can deal with epidemics of small-pox by means of isolation, without having recourse to vaccination. Those

Digitized by Google

who are familiar with the facts of the outbreaks of small-pox which have taken place at Leicester of late years know very well that whatever may be the theory of Leicester on this point it does not represent the practice in that town. For in Leicester, as elsewhere, when small-pox is prevalent there is always a run upon vaccination, and the medical officer of health, who has never had any delusions of this kind, has always had a free hand to vaccinate all whom he could induce to undergo the operation, including those who were most exposed to infection, such as hospital nurses and attendants. But if the sanitary authority of Leicester or any other place were to refuse to promote vaccination with the very moderate amount of coercion which will in future be associated with it, why should they not at least be required to show that they have provided in an adequate degree the resources which they claim to be an effective substitute for vaccination? They, in common with other opponents of vaccination, allege that isolation and disinfection are sufficient weapons with which to meet an outbreak of small-pox. Well, we have had some experience both at Gloucester and at Middlesbrough of what is needed to meet possible contingencies of this kind. Why should not the Local Government Board lay down a general proposition as to the minimum amount of resources for hospital accommodation and disinfection which such a town as Leicester should provide, and then hold an inquiry as to how far it had met these requirements? If the Leicester sanitary authority could show that they had efficiently armed themselves in this way they would have some claim to be entitled to disregard vaccination, but if Leicester or any other place where vaccination is formally discountenanced were to refuse or to neglect to comply with reasonable requirements in regard to providing the alternative for vaccination which the anti-vaccinists themselves affect to consider a sufficient protection the force of public opinion would be so strong against them that the Local Government Board would be well justified in bringing all the powers of the law, whether by *mandamus* or otherwise, to bear upon them to compel them at least to make such provision. It is only by compelling defaulting sanitary authorities to spend money in doing their duty that they can be brought to book. Such procedure is on all fours with that by which individuals who refuse to do their duty are punished. They are fined, but with this difference, that in their case the penalty is applied for the benefit of the community at large, instead of being primarily devoted to meeting their own needs, as it would be where a sanitary authority was compelled to spend money in providing for its special requirements. Hedged round with these conditions there would be something to be said for allowing the principle of local option in vaccination to have some scope for experimental application. At any rate, it would be placed under some control, which would be better than the present state of anarchy.

The vexed question of compulsion.—The Bill as it entered Committee was so drafted, as has been already seen, as to remove a good deal of the grievance by which the agitation against vaccination has been largely maintained. Prosecutions, which have been hitherto unlimited and in some cases scandalously multiplied, would be in future limited to two or possibly three. This of itself was a great gain. But the framers of the Bill failed to avail themselves of the opportunity which presented itself to them to use the power of prosecuting defaulters in a much more effective way than has been hitherto done. The 31st Section of the Act of 1867 gives power to prosecute the parent or custodian of any unvaccinated child until the child is fourteen years of age. The Jenner Society have urged in various documents which they have issued on the subject that if the power of prosecuting defaulters thus conferred by the Act of 1867 is to be retained as a test of the solidity of objection on the part of a defaulting parent, it is not expedient to use it more than once in infancy and that a second or third application of it, if employed at all, should be applied at later periods of the child's life, when first entering and when about to leave school. The object of so doing is, in the first place, to formally revive at these periods the requirements by the State of the vaccination of the child, in the second, to put the same pressure upon the parent at these two stages of the child's life as was applied in infancy. Such a procedure is thoroughly logical and defensible. For if the penalty test is defensible in infancy it is equally so at these two later periods, when the danger against which vaccination is a safeguard is greater both to the child and to the community than it is in infancy. Sir Walter Foster took the sense of the Committee on the penalty question generally by proposing what is commonly called a conscience clause, which, after all, when enforced in the way he proposes is only a penalty in modified form. For it cannot be denied that anything short of the power of escaping vaccination by signing a simple form of declaration, which can be made without any trouble or expense, is a penalty, especially to a poor man. On the other hand, any form of exemption which does not go beyond such a declaration is so feeble a test of the solidity of a man's objection that it is practically no test at all. The Committee decided, though by a small majority, that it was not expedient to abandon the test which the law at present imposes limited in the way proposed in the Bill. Sir William Priestley then proposed and carried an amendment which adopts the course suggested by the Jenner Society of limiting the prosecutions in infancy to one, under the 29th Section of the Act of 1867, and reserving the use of the 31st Section until the child arrives at the age of four. To this Sir William Priestley himself added the provision that if a parent "satisfies the court that he conscientiously believes vaccination would be prejudicial to the health of the said child," he is not liable to any further penalty or molestation. Nothing is said in this provision about costs, and as prosecutions cannot be initiated without incurring costs of some kind it is doubtful who is to be left to pay them in case of successful evasion of the requirements of the law. Now, it cannot be denied that this clause is open to all the objections on the score of logic and consistency which have been urged against the adoption of exemption by declaration in infancy. It is true that it revives the obligation of the law once, but it does so in a very attenuated form. It prescribes a penalty as the price of exemption, but what that penalty is precisely to be is left somewhat obscure. It is, in fact, one of those compromises which are so often the price which has to be paid to buy off opposition.

Further amendments: rejection of Clause 7.—The foregoing notes on the Vaccination Bill were written before the recent debate on the report stage of the Bill. Only two material amendments have been made in it at that stage, but they are of some importance. The first was to strike out Clause 7, which was done by a majority of 270 to 49. The history of this clause is so curious and it throws such an interesting light on what may be called the internal economy of the Bill as to justify a little explanation of it. It was originally suggested by the committee of the Jenner Society, with other amendments, in a memorandum on the Bill which they issued. Sir William Priestley proposed it on behalf of Sir Walter Foster, by whom it was originally placed on the Orders of the Grand Committee. Mr. Chaplin accepted it without any demur and the Committee adopted it without any opposition. Its object was to enable local authorities to incur reasonable expenditure in diffusing information on the subject of small-pox and on the advantages of vaccination in preventing it. At the present time it is open to some doubt whether boards of guardians can incur such expenditure. By a liberal interpretation of a clause in the principal Vaccination Act it might be assumed that they could do so, but the point is not so clear as it might be, and it is quite certain that sanitary authorities, who are much more interested in preventing small-pox than boards of guardians are, have no such power. It appeared desirable that the doubts affecting the power of boards of guardians should be cleared up and that sanitary authorities should be distinctly empowered to diffuse information on a matter in which they are so greatly interested. On report of the clause Sir Charles Dilke moved its rejection on the plea that it might lead to friction between county councils and boards of guardians. How it could possibly do so he did not explain, and as there are numerous chairmen and other members of county councils in the House, none of whom supported this view of the matter, the fear may be dismissed as groundless. Sir Walter Foster, who had originally fathered the clause, strangely enough had nothing to say on its behalf and consented to its withdrawal. Mr. Gibson Bowles ingenuously objected to it because it would favour a "one-sided propaganda," and he appeared to be ignorant of the fact that the agitation against vaccination is maintained by a propaganda of a decidedly one-sided character. Mr. Chaplin repudiated responsibility for the clause but recognised its utility, and several members, chiefly on the Government side, protested against its rejection. Under these circumstances it might have been expected that it would easily pass, but to the general surprise Mr. Balfour pronounced against it and it

Digitized by Google

was lost. Mr. Balfour's explanation of his objection to the clause was even more remarkable than that of Sir Charles Dilke. He said that for a consideration he would undertake to produce a defence of vaccination which would inspire doubts in anyone who read it, and that it was not desirable to give boards of guardians a chance of making vaccination ridiculous. That Mr. Balfour, who is an admitted master of the art of clothing philosophic doubt in the garb of conscientious conviction, could travesty a defence of vaccination which would breed doubts in the mind of an unprejudiced reader is quite possible. But whether he would equally bamboozle the auditor of the Local Government Board, who would ultimately have to decide as to whether his defence was a travesty or not, is a different matter. Moreover, if so little confidence can be placed in boards of guardians that they cannot be trusted even to circulate literature in support of vaccination, how can Mr. Balfour justify their retention as vaccination authorities? A lamer excuse for a foregone conclusion was never offered. The real explanation of the sudden change of front in regard to this clause is very simple. The anti-vaccinationists outside the House had discovered, under the inspiration of the *Vaccination Inquirer*, the organ of the Anti-vaccination League, that a mistake had been made in not opposing the clause in Committee. Pressure was at once brought to bear on such members as could be influenced to reject the clause. All the non-official members who opposed it represent constituences in which the anti-vaccinationists are strong. It was a small sacrifice for them to burke the clause. But they could not have rejected it without the connivance of the Government. This was not likely to have been afforded had it not been for the fear of a reduction of the Government majority. Jonah was therefore flung to the waves, and sanitary authorities will be still left helpless in meeting the agitation against vaccination by the only means by which it can be withstood. The matter is not one of vital importance, but it points a moral which is still further illustrated by the course which the debate took on the more crucial question of the enforcement of the law. On this subject it is only necessary to point out that if the the Government had properly appreciated the difficulties of their position at the outset they might have made a concession to the opponents of vaccination which, though it would not have satisfied the Anti-vaccination League, would have effectually cut the ground from under the feet of the organised propaganda against vaccination, and they might at the same time have secured solid compensations for this concession in the direction of revaccination and of the general improvements of vaccination administration. They have now capitulated in a panic and are no longer masters of the situation. It will not be long before they find out their mistake, but it will in all probability be a long time before they will find such an opportunity for statesmanlike legislation as they have thus lost. A few more experiences like those of Gloucester and Middlesbrough will hurry it on, but meanwhile the administration of vaccination will be demoralised and, like the Sibylline books, the price that will have to be paid eventually for the neglected opportunities will be proportionately heavy.

Provisions not in the Bill.—Having thus dealt at some length with what the Bill as amended contains, it is only necessary to refer briefly to some provisions which it does not contain. First of all, it is entirely silent on the subject of revaccination, notwithstanding the strong representations made to the Government on the subject and the statement by Mr. Chaplin in debate on the second reading of the Bill that he would favourably consider any proposal made by Sir Walter Foster, who thereupon proposed an amendment in favour of it. The Bill, also, as has been before indicated, altogether ignores vaccination by private practitioners, who are to be as uncontrolled in deciding what is "sufficient" vaccination as they have hitherto been. Moreover, the sanitary authority will have as little power as it has at present to promote vaccination even in times of epidemic small-pox, and the medical officer of health will continue to have neither responsibility for, nor official connexion with, one of the most important branches of sanitary work. With these important matters, which lie at the bottom of the efficient promotion of vaccination, altogether ignored it is unnecessary to specify other points which are scarcely less essential in building up a system of effective administration. Some of these, to which it is unnecessary to allude here, were indicated in the memorandum on the Bill issued by the Jenner Society. It is, of course, not to be assumed for a moment that the Government are insensible to the desirability of incorporating all these provisions if they could have seen their way to do so. But, with the facilities for factious obstruction which the forms of the House of Commons offer it is practically impossible to deal with a subject of such a contentious character in a Bill which has any chance of getting through Parliament unless by a vigorous exercise of the closure or by buying off opposition with large concessions. The Vaccination Bill is only one of many illustrations of the increasing unfitness of Parliament, with its present antiquated regulations, for dealing with the legislative requirements which the ever-augmenting complexity of our social organisation demands.

In conclusion, as this meeting is held in a part of the United Kingdom by the experience of which the provision in the Vaccination Bill on the subject of enforced domiciliary visitation has been justified, it would be interesting to learn what that experience is at the present day compared with what it was when the Royal Commission took evidence on it seven years ago. It was then reported that vaccination prosecutions were almost unknown in Scotland; that there was practically no agitation against vaccination; and that no difficulty was experienced by those medical men who officially correspond with the public vaccinators of England in obtaining the vaccination at their own homes of the comparatively small percentage of Scotch children who were not vaccinated by private practitioners. In these matters one is inclined to ask, "Stands Scotland where it did?"

THE PATHOLOGY OF A FIT OF GOUT (PAROXYSMUS PODAGRÆ).[1]

BY GEORGE W. BALFOUR, M.D. ST. AND., LL.D. EDIN. & ST. AND.,
CONSULTING PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY.

APART from the sudden onset of pain the most striking phenomenon connected with a fit of gout is turgescence of the veins leading from the joint affected for some distance along the foot. Where there is inflammation there is always an unusual amount of blood passing through the part affected, and there is also considerable œdema, but the circulation is free and there is never any visible turgidity of the veins leading from it. When veins appear turgid and swollen we know that this must arise from some hindrance to the onward flow of the blood, from some pressure external to the vessel, as from a tumour, or from some internal obstruction as from a thrombus. Such obstacles are readily recognised and are not present in a fit of gout. In a gouty attack the turgid veins, after coursing a certain distance along the foot, empty themselves naturally into the contiguous vessels, and gentle pressure readily forces the blood onwards, though when the pressure is removed the veins at once refill by reflux from the neighbouring vessels. In a fit of gout there is no direct obstacle to the onward flow of the blood and the venous turgescence must be due to some other cause. But the only other possible cause of venous remora is the occurrence of a block in a terminal artery or in its arterioles or capillaries.

Now we know that gout may attack any part of the body, but an acute attack—a paroxysmus podagræ—is never found save in connexion with one of the smaller joints, and most commonly in connexion with the metatarso-phalangeal joint of the great toe, because it is only in these positions that the conditions necessary for its development are present. An attack begins with a sudden onset of pain of the most excruciating character, perfectly explicable by the theory of a sudden block in the circulation cutting off the supply of nutritious pabulum from the adjoining sensitive nerves. Pain, as Anstie has told us, is the prayer of the nerve for more and better blood, for better nourishment, and, indeed, the only pain which at all approaches gout in severity is that following the occlusion of an artery, either artificially, as in the treatment of aneurysm by compression, or naturally, as in the blocking of an artery by an embolus.

[1] A paper read before the Section of Medicine at the recent meeting of the British Medical Association.

Digitized by Google

or a thrombus, or the pain which precedes or follows an attack of Raynaud's disease. A stasis of the blood within the joint affected, however produced, may therefore be accepted as a perfectly rational explanation of the pain of gout.

The earliest visible sign of a gouty paroxysm is the appearance of turgid veins arising in the neighbourhood of the joint affected and running for some distance along the foot.[2] But stasis of the blood within the metatarso-phalangeal joint of a toe sufficient to cause the excruciating pain of gout is certain to be accompanied by the formation of an anæmic area in and around the joint, and naturally the veins connected with this area of negative pressure get filled by reflux from the contiguous valveless veins. The turgescence of these veins is in the foot somewhat favoured by gravity and it continues very evident until the veins reach a part where normal conditions of the circulation prevail—that is, where there is no longer any reflux because the veins have ceased to be valveless. While the veins have been gradually getting turgid plasma has been slowly accumulating within the area of negative pressure, and as the corpuscular elements have also escaped by diapedesis into the tissue interspaces and the red corpuscles readily part with their colouring matter to the plasma the turgid veins have not been long visible before we have a swelling in and around the joint, which becomes increasingly tense, stretching the skin and giving it a glistening appearance, all the more striking from the dusky redness due to the colouring matter of the red corpuscles. After a fit of gout the cartilages and other tissues about the joint are found to be infiltrated with crystals of urate of soda, a condition which is trifling after a first attack, but which increases with each succeeding paroxysm. This has been regarded by some as the result of the peculiar character of the gouty inflammation.[3] But from beginning to end of a gouty paroxysm there is neither sign nor symptom of inflammation and the presence of these crystals is susceptible of a simpler explanation. For in gout we know that the blood-plasma contains urates[4] which are not very soluble, and when the plasma accumulates within the anæmic area surrounding a gouty joint the salts slowly crystallise out of the extravascular fluid and get left behind when the serous part of the fluid is reabsorbed, infiltrating the joint, the cartilages, and the surrounding tissues and gradually accumulating after each succeeding paroxysm till they form those tophaceous deposits we know so well as the result of repeated attacks of gout. All the objective phenomena of a gouty paroxysm are thus readily explicable on the supposition of a stasis (or block) in the capillaries of the affected joint, and so far as I can see they are not to be explained by any other theory whatever.

There are also other facts connected with a fit of gout which go to confirm the theory propounded. First, we know that though the general organism of a patient suffering from a fit of gout is in a state of moderate pyrexia (100° to 102° F.), yet the temperature of the distal extremity of the affected toe itself is always subnormal (95·5° to 97°).[5] This apyretic state of the distal extremity of the affected toe is quite inconsistent with the presence of inflammation and seems only to be explained by an arrest of the circulation in the joint implicated. Second, there are some curious facts connected with the prophylaxis and the cure of gout which seem wholly inexplicable except on the supposition that the circulation is mainly at fault and that the prevention or removal of a stasis is sufficient to ward off or to cure an attack. In regard to prophylaxis we have the story that Mr. Apperley—the "Nimrod" of old times—tells us of a friend who after a skinful of wine and other good things always walked off the soles of his pumps before going home to bed in order to ward off a gouty attack, and this he did successfully and without damage to the end of his days. Cullen also tells us of a man who on the first premonition of an attack took his dog and his gun and walked it off.[6] Sir William Temple narrates that the Rhynegrave, who was killed before Maestricht in 1676 and was his personal friend, on the first indication of a paroxysm went out immediately, whatever the weather, and walked as long as he was able, "pressing most upon the foot that threatened him; when he came home he went to a warm bed and was rubbed very well and chiefly upon the place where the pain began." If the attack continued or returned next day the same course was pursued, so that he was never laid up with gout, and he thought so well of his treatment that he strongly recommended it to his son should he ever be attacked in a similar manner.[7] Temple also tells us of one of his brother's gamekeepers very subject to gout, but who never laid himself up. When attacked he busied himself with his deer or his stud, walking about from morning to night in spite of the pain.[8] And the late Dr. William Gairdner of London was acquainted with a lively old gentleman of eighty-five, who, when seized with gout, always replied to the remonstrances of his family and his physicians: "I'll walk it off," quaintly adding, "go to bed with the gout and it will surely go to bed with you and be mighty bad company"[9]—a remark that recalls the statement of Sir William Temple that gout haunts chiefly those who treat it as a friend and not as an enemy, who "carry it to bed with them and keep it soft and warm, and, indeed, lay up the gout for two or three months while they give out that the gout lays up them."[10]

As a method of treatment we hear but little of massage in medical literature, yet it must have been occasionally employed, as when Boerhaave[11] in his 1275th aphorism, section 8, speaks of curing gout "*exercitio magno, continuato, equitationis in aëre puro, tum frictionibus, motibusque partium sæpe iteratis*," the context shows that he speaks of these as approved methods to employ in the cure of an acute attack, and not merely as means to be used for the removal of the rigidity of gouty limbs during the intervals of comparative health. Cullen has also recorded some curious instances in which enforced exertion—not exactly carried out with due professional care—was followed by the sudden cure of gout. One patient, long confined to bed with gout, rose and ran off as fast as he could when his neighbour's house took fire. Another patient's provoked antagonist dressed himself up as a spectre, threw the poor patient over his shoulder, and carried him downstairs with his feet bumping on each step. As soon as the ill-used man reached the bottom of the stairs he found his legs and ran upstairs fast enough. It may be readily supposed that such rough empirical treatment, however successful, was not likely to be much approved of by the patients submitted to it or to be adopted by more regular practitioners. When the trifling succussion caused by merely crossing the floor to the bedside is liable to provoke intolerable agony he must be a bold practitioner who would venture to propose the application of massage to the offending digit itself. Yet this has not only been proposed but actually carried out with the most surprising results.

During the first half of this century a namesake of my own—Dr. William Balfour—practised in Edinburgh,[12] and had a great reputation for his successful treatment of rheumatic affections by the various methods we now comprise under the term massage. Occasionally, also, he attacked more acute ailments with a boldness and success which were truly remarkable. In the *Edinburgh Medical and Surgical Journal* for October, 1816,[13] Dr. Balfour relates several cases of acute gout treated by compression, friction, and percussion. These cases are all remarkable and all perfectly successful. I shall only quote one, as this is sufficient to show his method and its result.

CASE 1.—The patient, a man aged forty-seven years, of a cholerico-sanguine temperament and full habit of body, woke in the morning of July 22nd with violent pain in the balls of both great toes, particularly at the flexures of the joints. "When I visited him at eleven o'clock forenoon the parts were swelled, red, tense, and shining. The inflammation and pain were confined almost exclusively to the balls of the great toes, except that in the left, which was by much the worst, the pain reached upwards about half-way along the metatarsal bone. The patient experienced continual excruciating pain even when at perfect rest; his countenance indicated considerable distress, and he complained of sickness, general uneasiness and oppression; pulse 82. When I entered my patient's room he told me that if I intended to

apply friction to the parts affected, he was afraid he could not suffer it, for he had attempted that himself, but might as well have applied 'living fire.' I told him I knew that friction was quite inapplicable to his case as it then stood, but that I would, notwithstanding, employ mechanical means for moderating the paroxysm, and I hoped with complete success. I therefore grasped the ball of the toe in my hand, applying pressure gradually to a very considerable degree. Slight pressure gave pain; heavy pressure none. In this manner I compressed the parts, sometimes with one hand, at other times betwixt both hands, for about ten minutes, now and then interposing gentle percussion, and then applied a thin flannel bandage. Ordered a brisk purgative of senna and sulphate of magnesia. In the evening the patient said he had considerably less pain, or rather none at all, from the moment I left him, but he had a good deal of cold shivering during the day. His pulse was 100. The swelling and redness of the parts had much abated and motion of the affected joints was practicable. Compression and percussion were re-applied and were much better borne than in the earlier part of the day. Next morning the patient was found to have slept all night without interruption. His pulse was 80; pain, swelling, and redness of the parts almost entirely gone and he could suffer them to be handled with the utmost freedom. He walked very well. Compression and percussion were applied in the morning, in the evening, and again next morning, after which the patient went abroad in the prosecution of his business—on the third day of his attack."

The graphic account just given leaves no room for any doubt as to the nature of the disease or the success of the cure, and I am sure you will agree with me that any method able to cure acute gout in one or two *séances* is well worthy of the consideration both of patients and physicians. Not many, however, would have the nerve to apply such a cure or the courage to submit to it, and though Dr. Balfour has published several similar cases he has not, so far as I know, had many followers. Nevertheless I have recently heard that one old friend of my own, who saw a good deal of acute gout in the beer-drinking district in which he practised, was in the habit of benumbing the affected joint by painting it with Fleming's tincture of aconite and then rapidly completing the cure by massage.

The history of gout is not wholly comprised in a stasis of the circulation in the metatarso-phalangeal joint of the great or of any other toe, but if this is accepted as the explanation of an acute attack much is made plain which seems now mysterious and we obtain a clue sufficient to guide us through the labyrinth of symptoms presented by this protean malady. I am not desirous, nor have we time, to go deeper into the history of gout at present: I merely wish to bring before the profession for their consideration this simple theory of the cause of a paroxysmus podagræ as it seems to be the only explanation capable of interpreting the phenomena observed and also of adequately accounting for the success of the methods of prophylaxis and of cure which I have just described.

Edinburgh.

THE OPERATION OF GASTROSTOMY PERFORMED BY THE KADER-SENN METHOD,

WITH TWO CASES SUCCESSFULLY SO TREATED.

BY A. ERNEST MAYLARD, M.B., B.S. LOND.,
SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

So simple, so expeditiously effected, and withal with such excellent result, is the method of Kader-Senn for performing gastrostomy that its mode of execution needs only to be more widely known to be, I venture to think, almost universally adopted. This is high praise to accord to any particular method employed for whatever purpose, and yet I feel impelled to give it, although it is an opinion based upon its adoption in two cases only; but with simply these two cases it is difficult to see where success should fail to be obtained in an unlimited series. Every operation appeals to the surgeon in proportion to its simplicity, and when that simplicity ensures success in the object aimed at little else is required to commend it.

The numerous modifications which have from time to time been introduced all aim at the one object of preventing leakage from the stomach through the artificially established orifice. Some of these modifications have unquestionably attained this end. Thus those introduced by Frank, Witzel, Hahn, von Hacker, Gérard, and others have all more or less succeeded in this respect. But as contrasted with the Kader-Senn method they cannot lay claim to such simplicity and rapidity of execution. Whether this operation has been tried already by British surgeons I do not know, but so far as it has been practised in America those who have recorded cases speak unanimously in its favour. The following is the account of the operation as described by Senn[1]: "The operation consists of an abdominal incision of about 4 in. in length, and which can be made in any location deemed advisable, as no abdominal muscular structures are required for sphincter action. However, Fenger's incision, which is parallel to the left costal border left of the rectus muscle, is preferable. The stomach is seized as near the great curvature as possible and a cone is formed by an assistant who holds the apex with his fingers or a tissue forceps. Two puckering strings of heavy chromicised catgut are placed parallel to each other about 2½ in. below the apex of the cone. These sutures include the serous and muscular coats of the stomach. These sutures are next drawn taut and tied, forming a constriction or neck. ..... The stomach is now ready to be fastened into the parietal wound. This is done with interrupted silk sutures, which include ..... the peritoneal and muscular coats of the stomach and all the abdominal wall except the skin. The rest of the abdominal wound is now closed with silkworm sutures, leaving only that portion of the stomach visible which is to form the valve. This concludes the first stage of the operation. The second stage can be done at this time or can be deferred for forty-eight hours until adhesions have formed. This consists of an incision about half an inch in length in the centre in the portion of the stomach exposed. A rubber tube is inserted through the opening into the stomach. The stomach wall is now inverted, forming a circular valve. The inversion is secured by Lembert sutures of silk. The tube is now withdrawn and the operation is completed. If properly performed the valve should be below the level of the external integument. The retraction is greatly favoured by subsequent contraction of the wound."

The following is an account of the two cases upon which this operation—with some slight modification to be afterwards referred to—was successfully performed. The brief abstract given in each case is from the report taken by the resident assistant, Dr. Vost.

CASE 1.—A man, aged fifty-seven years, was admitted to the Victoria Infirmary, Glasgow, suffering from carcinoma of the œsophagus. His illness commenced about three months prior to admission, at which time he began to find difficulty in swallowing solids, and that every attempt was immediately followed by their ejection. Fluids he could always keep down. When he tried to swallow anything solid he was conscious of it sticking in his gullet and pointed to a place at the level of the ensiform cartilage where it caused severe pain. His bowels were regular, his tongue was moist and slightly furred. He had lost flesh and looked emaciated, with a dry rough skin. He was much troubled with flatulence. An olivary bougie, which passed down 16 in., could not be made to enter the stomach, but with a railway bougie the internal filament could be passed into the stomach. On Nov. 8th the patient was prepared in the usual way by the administration of an aperient. On Nov. 9th, immediately prior to the operation, copious water enemata were given, followed by a nutrient enema. With the assistance of Dr. Grant Andrew, Dr. Vost, and Dr. Fleming, gastrostomy was performed. A median incision was made between the umbilicus and the sternum. The stomach was sought for and found to be much contracted, lying well up under the liver to the left. A digital examination did not definitely reveal any growth towards the cardiac end, but some small suspicious nodules could be felt. The stomach was then pulled up by a fixation stitch and the circumference of a circle measuring about from 1½ in. to 2 in. in diameter carefully stitched to the parietal peritoneum. The wound was then closed above and below. The cone-shaped projecting portion of the stomach was then encircled at its base by two purse-string sutures, the ends of which came out at

[1] Journal of the American Medical Association, 1896, vol. xxvii., p. 1143.

Digitized by Google

opposite points. The apex of the cone was then incised and the stomach was opened. A gum elastic catheter, No. 12, was inserted into the stomach for about 3 in. and secured by a stitch to the gastric parietes at the apex of the cone. By pushing in the catheter the cone was invaginated, and then by drawing upon the purse-string stitches the gastric parietes were puckered up and made to embrace the catheter so that it became secured in position. The catheter was cut nearly flush with the wound and a small plug was inserted. The operation lasted about an hour. The patient took chloroform well and rallied well. He proved in his convalescence a very restless patient and so retarded somewhat the healing of the wound. However, his recovery eventually was perfect. He left the infirmary about two months after the operation (Jan. 25th, 1898) and returned to report himself on Feb. 16th, when the fistula was found to be all that could be desired. There was no leakage and feeding was easily accomplished with the catheter attached to an india-rubber tube and a glass funnel or filler.

CASE 2.—A woman, aged sixty years, was admitted to the Victoria Infirmary on Nov. 9th, 1897, suffering from difficulty in swallowing solids. She stated that about two months previously her trouble commenced, when every now and again solid food which she took would be immediately returned. Fluids could be taken without difficulty. She experienced no pain except when endeavouring to swallow something solid and then referred the sense of discomfort to the neck about opposite the cricoid cartilage. She had usually to take aperient medicine to obtain a movement of the bowels. She stated that she had lost strength and flesh. In appearance she was much emaciated, with a pale, dry, rough skin. The passage of an olivary bougie encountered obstruction about 13 in. from the incisor teeth. After the usual preparation of the patient gastrostomy was performed on Jan. 1st with the assistance of Dr. Grant Andrew, Dr. Vost, and Dr. Fleming. The only difference in the method of operating from that employed in the above case was the use of a smaller size gum-elastic catheter (No. 8). The patient took chloroform well and rallied without any shock. The operation lasted thirty-five minutes. The patient made a rapid and uninterrupted recovery, leaving the infirmary on Jan. 20th, 1898. She was able to feed herself, as in the first case, by the aid of a catheter, rubber tube, and filler. There was absolutely no leakage of the contents of the stomach.

By referring to the illustration, which represents the method employed in these two cases, it will be seen that the

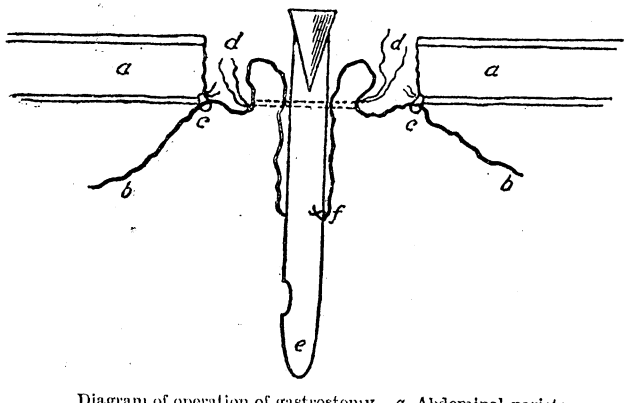

Diagram of operation of gastrostomy. *a*, Abdominal parietes. *b*, Gastric parietes. *c*, Fixation stomach stitches. *d*, Purse-string stitches. *e*, Catheter. *f*, Fixation stitch of catheter and stomach.

operation is in many respects simply a modification of that introduced by Witzel. Instead, however, of the tube being fixed in an oblique fold of the stomach wall it is secured in a direct channel. According to Senn, Kader of Breslau had anticipated him in the adoption of this modification, with only some slight difference in the mode of suturing, and if, therefore, a name should be applied to it it would be better to designate it the Kader-Senn operation. Senn himself in his original description calls it "a circular valve method"; but this, while it to some extent indicates the result obtained, does not wholly convey to the mind the practical mode of procedure, which is the inversion and fixation of a cone of the gastric parietes with a permanent orifice at its apex. Naturally this fixed cone tends to collapse upon its base when the supporting gum-elastic tube is removed, and in so doing acts as a circular valve inhibiting the escape of the gastric contents.

In reviewing certain features connected with these cases it will be observed that in neither was the patient *in extremis*. Both patients could take plenty of fluid nourishment and therefore from the aspect of necessity there was no need of the operation; but, on the other hand, in view of the certainty that sooner or later difficulty would arise in the ingestion of fluids and the patient's strength and general vitality become gravely impaired, it appeared at least expedient that the favourable opportunity afforded should not be missed and the operation therefore performed without undue delay. This particular aspect of the question becomes all the more feasible when we are able to ensure the extreme probability of no immediate ill effects from the operation and the almost absolute certainty that the patient's sufferings if relieved in one way would not be augmented in another, as by the frequently troublesome irritant after-effects dependent upon the escape of the acid gastric juice through the fistula. It has been suggested that the operation should be carried out in two stages, but I believe that when the stitching is all carefully executed there need be no fear regarding the opening of the stomach at the one operation. A properly fitted plug would effectually prevent any escape through the catheter, and it is quite impossible for any leakage to take place along its sides. If thought advisable in severe and advanced cases fluid nourishment can be safely administered by the catheter at the operation, but otherwise a day or two may elapse before making use of the artificial opening. While in such cases as those above narrated there is no necessity for the administration of fluids other than by the mouth there is a distinct advantage in doing so. For what we found was that in both instances the rest which accrued to the strictured part of the gullet from the temporary introduction of all food by the catheter allowed them to take nourishment subsequently by the mouth of a much more substantial consistency than they had previously been able to do and this, too, without the pain which, in the case of the man, had always been of a distressing character. Porridge, bread-sop, and farinaceous puddings were among some of the foods of a more solid nature which they were now able to swallow with relish and comparative ease.

As regards the size of the tube used and its period of removal I employed in the first case a No. 12 gum-elastic catheter and removed it on the fourth day. In the second I used a No. 8 and allowed it to remain in until it became sufficiently loose to be extracted, which was in about a fortnight. When the latter was withdrawn the intra-gastric portion did not seem to have undergone any digestion. Without going into the reasons I may say that I should prefer in future the larger size catheter and its retention until loosened.

Concerning the after-treatment some care is necessarily required to prevent closure of the fistula. In the second case, in which the No. 8 catheter was used, there was a distinct tendency in this direction. We at first found that the daily passage of a bougie or catheter sufficed to maintain its patency, but soon the difficulty so increased that often in the morning the orifice was found glued over and the patient was unable without assistance to insert the catheter. This, however, was easily obviated by using a small vulcanite shield with a bougie-like projection one and a half inches long attached to the centre of one surface. This was tied in like a tracheotomy tube and inserted into the fistula over night. By this simple contrivance the patient no longer had any difficulty in inserting her catheter for feeding purposes when she required to do so.

In summing up the advantages of this method of performing gastrostomy I think it may justly lay claim to the following:—(1) the extreme simplicity and safety of the operation and its rapidity of performance; (2) the almost practical certainty that no subsequent leakage of the gastric contents will take place; and (3) the safety of the operation and the absence of any remote ill effects renders its early performance advisable, that is, as soon as solids can no longer be taken. In connexion with this last clause there may be added the still further advantage gained by the patient in being able to take more substantial nourishment by the mouth and with less pain. This relief no doubt results from the rest which the diseased part of the gullet derives from all food being conveyed to the stomach by another channel. It

Digitized by Google

admits of the subsidence of any irritative inflammation about the seat of the stricture so that exudates are absorbed and muscular spasm is lessened. It is therefore impossible not to conclude that though the operation of gastrostomy successfully executed is only palliative, it is nevertheless likely to be the means of prolonging life longer if performed early than when the period of necessity has been reached; in other words, before and not after difficulty in swallowing fluids has occurred.

Glasgow.

VACCINATION RASHES.

BY ROBERT J. CARTER, M.D. LOND.,
ASSISTANT PHYSICIAN TO THE WESTERN SKIN HOSPITAL.

IT is a question of some importance what precisely may be the influence of vaccination in the production of various skin eruptions. Has vaccinia such an effect upon the human organism as to render the skin more liable to become affected by rashes, or are we to regard as a mere coincidence the fact, which is undoubted, that children, and indeed adults, may after vaccination suffer from various forms of skin eruptions? The truth would appear to be between these two extremes. Vaccination is undoubtedly responsible directly for some forms of eruption, and indirectly in a remote degree for others; but it is manifestly unfair to ascribe to vaccination an eruption which appears weeks, or even months after the lesion produced by the operation has soundly healed. In my experience post-vaccinal rashes are uncommon—that is to say, such rashes as may occur within a period of time in which it may reasonably be supposed that the course of vaccinia has in some way or other been instrumental in causing their appearance. What this limit of time after vaccination may be at which eruptions of the skin may appear, due indirectly or directly to the operation, it is difficult to state precisely. Dr. Crocker states that in no case can an eczema be due to vaccination where the vaccine pustule has completely healed before the appearance of the eczema. Personally I should hesitate to ascribe any rash as due to vaccination except vaccino-syphilis, when after examination the site of the vaccination is found soundly healed, which may roughly be taken as occurring from 4 to 5 weeks after the operation. The results of recent researches have made it clear exactly what vaccination is and we are consequently better able to gauge its likelihood of causing skin affections as compared with other acquired diseases. That true vaccinia may result from the inoculation of a modified attenuated variolous lymph cannot now be questioned. Variolous lymph by its passage through a series of calves becomes so attenuated and modified that it can no longer produce violent constitutional effects with a generalised eruption, but only a slight constitutional disturbance and an eruption limited to the points of inoculation, and a condition of the organism is produced which renders it immune against variola or vaccinia for a variable period of time. How this immunity is produced, whether by the organisms of the vaccine virus multiplying in the body and by their life and growth producing complex chemical bodies, which by absorption produce a change in the human tissues, rendering them immune, or, as Dr. Cory suggests, whether the whole production of such chemical bodies takes place in the vaccine vesicles, may be an interesting speculation, but leads nowhere. What interests us more is the certain fact that for our purpose vaccinia may be practically classed amongst the other exanthemata, that it is a constitutional disease which more or less profoundly affects the whole of the tissues of the human organism in which it occurs. That some tissues in the same organism are affected more profoundly than others is a well-known clinical feature in every constitutional disease and it would appear quite easy to conceive that in certain individuals vaccinia may produce a condition of cell change and tissue alteration in the skin causing the appearance of a rash, the type of such rash varying with the individual peculiarity of the skin—a peculiarity not of texture, complexion, &c., but physiological and vital. These remarks only refer to what are termed "pure vaccination rashes," that is, due to the inoculation of pure vaccine virus and not to extraneously introduced germs. The connexion between vaccination and the eruptions due to extraneously introduced germs is absolutely one of cause and effect and requires here no further discussion. Owing to the enormous percentage of children vaccinated in the present day (practically in London over 90 per cent.) had vaccinia much influence as a causative agent in the production of skin affections surely they would have increased *pari passu* with vaccination. This I venture to doubt, for a reference to writers of the pre-vaccination days certainly leaves one with the impression that such a disease as infantile eczema was as common then as now. As far as I have been able to ascertain there are no published figures as to the possible frequency with which post-vaccinal rashes may occur and, in fact, the whole literature of the subject is very meagre. As a possible result of the paucity of such literature and references in standard works many rashes are ascribed to vaccination, not only by the parents of children, but by medical practitioners, which have absolutely no connexion with vaccination either near or remote. A case of generalised eczema wrongly ascribed by a medical practitioner to vaccination is a centre from which all kinds of anti-vaccinationist poison emanate. The possible dangers of vaccination are absolute and quite real enough without the invention of bogies to frighten weak-minded people about an operation, which is probably the most important to the community at large of any we are ever called upon to perform.

It is true that "from their rarity post-vaccinal rashes are unimportant," to quote the words with which one writer dismisses the subject, but it appears to be of the utmost importance that every medical practitioner should have a precise and definite knowledge of the subject so that he may successfully combat, on the one hand, the prejudices of the parents and the glaring misstatements of the anti-vaccinationists on the other, and to be able readily to demonstrate the fallacy of the *post hoc propter hoc* argument so often and so dangerously applied to vaccination and subsequent rashes.

Vaccination rashes have been variously classified. Dr. Crocker's modification of the one by Mr. Malcolm Morris would appear to be the most complete, and, with an addition of my own, is the one I shall use as a basis for my remarks.

CLASSIFICATION OF VACCINATION RASHES.

Group I.—Eruptions resulting from pure vaccine inoculation. *A*, Secondary local inoculation of vaccine. *B*, Eruptions before the vesicles form, urticaria, erythema multiforme, vesicular and bullous eruptions. *C*, Eruptions after formation of the vesicles due to the absorption of the virus: (*a*) morbilliform, scarlatiniform and diffuse erythema, erythema multiforme, vaccine lichen, purpura; and (*b*) generalised vaccinia. *D*, Sequelæ of vaccination, eczema, psoriasis, pemphigus, urticaria, and congenital syphilitic rashes.

Group II.—Eruptions due to the vaccine plus some other virus. *A*, Introduced at the time of vaccination: (*a*) producing local disease, impetigo contagiosa, or other form of superficial inflammation; and (*b*) producing constitutional disease, syphilis, leprosy, and tuberculosis. *B*, Introduced after development and rupture of the vesicles (about the eighth day), erysipelas, cellulitis, impetigo contagiosa, furunculosis, gangrene local or disseminate, pyæmia.

This classification shows how varied in character post-vaccinal rashes may be and that they are almost as numerous as there are rashes to which an individual is liable. What determines the precise nature of the skin manifestation is, as I suggested above, a physiological and vital peculiarity of the tissue, or what is more popularly called "the idiosyncracy of the patient." That this must be is evident from the fact that of several children vaccinated from one source only one may exhibit post-vaccinal rash, or if there be two the rashes are of a different nature. The fact also that post-vaccinal rashes are even more frequent (according to the authorities) after vaccination with calf lymph than with humanised lymph points in a similar direction. It is a well-known clinical fact that local irritations in susceptible individuals may produce generalised skin eruptions. The wet napkin in infants, a chronic nasal catarrh, profuse perspiration, the use of certain irritants for the purposes of trade, and many others may, and indeed do, produce an inflammatory reaction in the skin by no means confined to the point of contact. Equally, then, vaccination in certain cases, the local irritation in the arm having superadded to it

Digitized by Google

the constitutional effects of vaccination, is liable to produce skin eruptions the exact type of which depends upon some peculiarity of the individual tissues, about which we know nothing and can surmise less We may now discuss more or less in detail the classification of post vaccinal rashes given above.

In Group I. under section *A* we have the secondary inoculation of vaccine. This may be auto-inoculation or accidental as apart from vaccination. As an instance of the latter some time ago I saw a female, seventy-two years of age, with a typical vaccine vesicle on the cheek. This was the result of nursing an infant whose vaccine vesicles had been opened on the eighth day, whilst on her cheek was a scratched papule which allowed the introduction of the lymph from the child's arm. Many such accidents have been recorded: vaccine vesicles on the eyelids, where their resemblance to primary syphilitic sores renders them important, on the tongue, and a remarkable case where a child suffering from eczema of the face and scalp sleeping with an elder child who had recently been vaccinated was inoculated by the latter, so that the whole eczematous area became the seat of vaccinal vesicles. It is a noteworthy point in secondary auto-inoculation that the secondary vesicles are more rapid in their formation than the primary and reach maturity almost as quickly.

Subsection B.—Urticaria may follow vaccination in infants just as in adults it may arise from apparently most trivial causes. It, however, differs from the urticaria of adults and presents the well-known clinical picture of urticaria papulosa, an affection most difficult to treat, resisting more or less effectually all therapeutic measures to yield at length to the lapse of time. Of the erythema multiforme, vesicular and bullous eruptions mentioned in the classification, but few writers even mention them, and then only by name; personally I have never seen such post-vaccinal rashes occurring before the formation of the vesicles.

Subsection C.—In this subsection the eruptions are due to the absorption of the vaccine virus and divide themselves naturally into two groups: (*a*) morbilliform, scarlatiniform, and diffuse erythema, erythema multiforme, vaccine lichen, purpura, and (*b*) generalised vaccinia. Under (*a*) it is curious to note that the morbilliform, scarlatiniform, diffuse erythema and purpura may all occur preceding the appearance of the exanthematic manifestation of small-pox. May not a peculiar condition of tissue in the organism reacting to the poison of variola react similarly to vaccinia? Certain it is that in both cases they occur but rarely. With the title roseola, erythema vaccinal (French), roseola vaccinia (German), occurs a fairly common erythematous eruption which some observers describe as the commonest form of post-vaccinal eruption. It appears about from the eighth to the eleventh day, but according to Hebra as early as the third or as late as the eighteenth day after vaccination. Kaposi describes it as the most frequent complication of vaccinia and states that it commences around the vaccine vesicle and gradually spreads over the body. In my experience it is a rosy red rash not unlike measles, the macules varying from a pin's point in size to the size of a five-shilling piece. It is not attended with any constitutional symptoms and fades after three or four days without any desquamation. Dr. Radcliffe Crocker describes a vaccine lichen which he considers the commonest post-vaccinal eruption. According to his description it may be papular, papulo-vesicular, pustular, rarely bullous, appearing on from the fourth to the eighteenth day, most usually on the eighth day. It commences on the arms and by successive crops may spread over a considerable part of the whole body, evenly distributed, sometimes becoming circinate. The papules are acuminate, pin's-point sized, bright red, and may remain so to the end, usually discrete, but occasionally coalesce into patches, often many of the papules are crowned with small vesicles or pustules and occasionally the whole eruption may be vesicular, such vesicles coalescing and becoming bullous, as recorded by Behrend. The rash lasts usually a few days, but occasionally successive crops appear attended by considerable itching, resembling Hutchinson's varicella prurigo. This account, taken from Dr. Radcliffe Crocker's book on Diseases of the Skin, corresponds closely with the vaccinal miliaria described by Dauchez in his work on vaccination rashes. Dr. Colcott Fox suggests that the different phases of vaccine lichen probably represent stages of the same inflammatory process. Both Behrend and Crocker have recorded cases of typical post-vaccinal erythema multiforme,

A purpuric rash may occur after vaccination in cachectic children. Cases have been reported by Gregory and Dauchez but are extremely rare. Under (*b*) generalised vaccinia is probably the most important of Subsection C. Under exceptional circumstances, chiefly after vaccination with calf lymph, the vaccine eruption, instead of being confined to the points of inoculation, is more or less widely spread over the body. It is still a debatable question whether these cases are due to general blood infection or whether the secondary vesicles are the result of auto-inoculation. According to the various writers the rash appears about the eighth day and its course resembles that of a vaccine vesicle. In the fatal cases inflammation and sloughing take place at the site of the vesicles, producing a condition exactly resembling varicella gangrenosa. In this country Mr. Hutchinson has seen and recorded several such cases. Dr. Cory, the Local Government Board Inspector, in his recent work describes cases similar to varicella gangrenosa as due to disseminated tubercle, but does not mention generalised vaccinia. Dr. Colcott Fox states that they are always the result of auto-inoculation. French dermatologists are generally agreed that there are two distinct kinds of generalised vaccinia (*a*) appearing spontaneously and (*b*) the result of auto-inoculation.

Subsection D comprises the sequelæ of vaccination—viz., eczema, psoriasis, pemphigus, urticaria, and congenital syphilitic rashes. Of these from its frequency eczema is important. Dermatologists differ in their opinions as to the frequency of eczema caused by vaccination, but all appear to agree with Dr. Crocker that no case should be ascribed to vaccination which has appeared after the vaccination has soundly healed. This consensus of opinion clears the ground and effectually disposes of the very large majority of infantile eczemas ascribed by parents to vaccination. A curious well-authenticated clinical observation is that vaccination sometimes cures an attack of eczema, and indeed has been recommended as a legitimate form of treatment not only in adults but in children. In the latter, however, when the eczema is acute it is attended with great risk owing to the possibility of auto-inoculation. There can be no doubt that in predisposed people eczema may follow vaccination, as it might any other form of dermatitis, however produced, but there is nothing in vaccinia *per se* which can cause an outbreak of the disease. What this predisposition to eczematous forms of dermatitis consists of, in the present state of our knowledge, it is impossible to say definitely. It has been explained as "a want of resistance in the epithelial structure" or as "vulnerable epithelium," but such explanations do not assist us much. Certain it is that in the predisposed any slight local irritation may give rise to a widespread attack of eczema. When following vaccination eczema may commence in the region of the vesicles and gradually spread, or, more rarely, a large area of the skin may become suddenly attacked. It usually appears on or about the tenth day of the vaccinal period and in its course and amenability to treatment would appear exactly to resemble eczema of other origin.

Post-vaccinal psoriasis is sufficiently rare to be a clinical curiosity. Chambard has described one case and Rohè two acute cases. Pemphigus is barely mentioned in French and English literature as following vaccination. The German dermatologists describe it, however, as occurring occasionally in weakly infants and they differentiate it from ordinary pemphigus due to cachexia on account of the fact that the prognosis in post-vaccinal pemphigus is distinctly favourable, physically their appearance being identical. Urticaria may occur as a sequela in point of time, but its association with vaccination would appear to be one of coincidence.

Congenital syphilitic rashes I place under the head of sequelæ, although apparently none of the various classifications published include them. In view of their extreme importance, both from a medical and lay point of view, their possible occurrence should be always borne in mind. That definite syphilitic rashes occur after vaccination it is impossible to deny, and it is of the utmost importance that not only should they be recognised as such, but that they should be attributed to their real source—namely, congenital infection. In Group II. syphilis occurring as the result of vaccination due to vaccine lymph plus the syphilitic virus will be treated, but in this group the clinical facts are quite dissimilar. The usual history obtained is that on or about the tenth day after vaccination an obviously syphilitic rash appeared. It hardly requires, except for the fact that so many misstatements have been made, that it should be

Digitized by Google

pointed out that such a syphilitic rash is due, not to syphilis introduced at the time of vaccination, but to a congenital infection. No rash in the case of inoculated syphilis ever appears before, at the very earliest, fifty days after inoculation. Apparently in the case of a child suffering from congenital syphilis, vaccinia produces enough local irritation and general constitutional disturbance to cause the appearance of skin manifestations, vaccination simply determining the date of the appearance of the skin lesions. Notwithstanding the fact that calves are absolutely immune against syphilis, congenital syphilitic rashes much more frequently appear after vaccination with calf than with humanised lymph.

Group II. consists of post-vaccinal rashes more or less preventable. Certainly Section A, those due to a virus plus the vaccine virus introduced at the operation of vaccination, are, with the exercise of ordinary precautions, absolutely preventable, and when occurring indicate culpable negligence on the part of the operator.

Subsection (a).—As a result of the introduction of pus cocci impetigo contagiosa may occur. This is a very rare accident, accidental inoculation taking place much more frequently after rupture of the vaccine vesicles. Short of true impetigo contagiosa slight forms of superficial inflammation may occur as a result of the introduction of one or other of the organisms found in pus.

Subsection (b).—The occasional inoculation of syphilis with vaccinia cannot be denied and is the great weapon in the hands of the anti-vaccinationists, but it has happened so rarely as practically to become a clinical curiosity, and with the introduction into general use of calf lymph will disappear altogether. When syphilis is inoculated simultaneously with vaccine virus, according to Fournier three alternatives present themselves: (1) syphilis is not transmitted but vaccinia is; (2) syphilis is transmitted and vaccinia fails; and (3) both are transmitted, some points of inoculation giving rise to typical vaccine vesicles, whilst later a syphilitic chancre or chancres appear at a point of inoculation when vaccinia has failed. Hutchinson states that a syphilitic chancre may follow typical vaccine vesicles in the same site. Fournier gives an excellent table in his clinical lecture on the subject, as to the differential diagnosis of vaccino-syphilis which is too long to give here. Briefly, he points out that the syphilitic chancre is limited to one or two points of inoculation, inflammation is slight, loss of substance is superficial, and the parchment induration is typical, not inflammatory. The acquired syphilitic rash appears at the earliest from fifty to ninety days after vaccination and requires in every case the existence of a specific sore at the site of the vaccination. In fact, vaccino-syphilis is in no way different from syphilis acquired in other ways and follows precisely the same course.

In this country the question of the introduction of leprosy with vaccinia is purely academic and the reported evidence from other countries is very conflicting. Tuberculosis is a disease which is confidently asserted by the anti-vaccinationists as likely to be introduced by vaccination. In Germany many experiments have been made with lymph from tuberculous patients with uniformly negative results. Attempts to inoculate the skin of guinea-pigs—animals most susceptible to tuberculosis—have invariably failed. That the skin of the human organism, however, is susceptible to the inoculation of tubercle cannot be denied, as cases have been reported where a local tuberculosis has been produced from tattooing and the like. Recently at the Dermatological Society of London a case was shown in which, although there was no microscopical or bacteriological evidence, yet the majority of those present agreed that the appearance was that of a local tuberculosis the result of vaccination. The question, however, of the transmission of the three diseases, syphilis, leprosy, and tuberculosis, by vaccination is probably solved by the introduction of glycerinated calf lymph by the new Vaccination Act of the present Government and ought to go a long way towards disarming what might be a legitimate criticism of vaccination.

Section B of Group II. comprises rashes due to the introduction of a virus after the formation and rupture of the vaccine vesicles. Of these by far the most important is erysipelas. It is possible that the pathogenic organism of erysipelas may be introduced into the patient on the eighth day by the operator opening the vesicles, but the accident must be excessively uncommon. After the opening or rupture of the vesicles the introduction of the erysipelas organism is not so uncommon and in the large majority of cases occurs when the child is living in bad hygienic surroundings. The characteristic rash of erysipelas generally appears within 24 hours after inoculation around the vesicles and spreads rapidly. In young infants it is very fatal and it was on this account that in the new Vaccination Act it was first proposed to raise the age limit at which vaccination must have been performed from three months (as now) to one year, statistics showing that the death-rate from erysipelas gradually diminishes with each succeeding month of the first year of life. Cellulitis mentioned in the classification is probably erysipelas complicated with pus cocci. Impetigo contagiosa is not uncommon after the rupture of the vesicles, around which it spreads and by the child's fingers may be carried to other parts of the body. Furunculosis is described as occurring as the result of the absorption of pus cocci into the system, their dissemination and ultimate arrest in the skin.

Gangrene local or disseminate. A local gangrenous action the result of septic poisoning may sometimes be seen at the site of the vaccination. A large black slough forms, which when detached leaves a deep ulcer which takes weeks to heal. Clement Lucas has reported a fatal case in an infant three months old. Disseminated gangrene the result of vaccinia is an exactly similar condition to that described as varicella gangrenosa. The lesions commence as a pin's-head sized papulo-pustule generally on the vaccinated arm and appear all over the body in crops. The pustule ruptures, a scab forms with an inflammatory acrola, and the centre becomes a black slough. Barlow has pointed out that the majority of cases, whether occurring after varicella or vaccinia, are associated with tuberculosis.

Cases of pyæmia after vaccination have been reported. As clinical curiosities may be mentioned the case published by Diday where a growth of hair took place around the cicatrix of a vaccination performed on the anterior part of the thigh of an infant eleven months old, and the occasional occurrence of keloid in the vaccination cicatrix, two cases of which have been reported.

Acacia-road, N.W.

NOTES ON THE

LOCALISATION OF A CENTRE IN THE BRAIN CORTEX FOR RAISING THE UPPER EYELID.

BY W. HARTLEY BUNTING, M.D., F.R.C.S. EDIN.

ALTHOUGH most of the motor centres in the brain cortex have for some time been accurately defined the centre for raising the upper eyelid is as yet uncertain. The very existence of such a centre has indeed been doubted by some, who hold that the centre for the levator palpebræ superioris along with that for all the extrinsic muscles of the eyeball is intracortical and is situated somewhere in the region of the corpora quadrigemina. I think, however, that there is strong evidence to show that a cortical centre does exist and that it is situated far forward in the general motor area. There are some difficulties which present themselves in the way of experimentally localising this centre. In the first place, since the eyelids on the two sides under normal conditions act together, one finds that the centres in the two halves of the brain for raising the lid are so intimately associated that compensation after destruction of the centre on one side readily takes place and ptosis is frequently not observed at all, or, if noted, it is quite temporary, the opposite side taking on the function; this theory was first advanced by Wernicke. Horsley as the result of the study of a clinical case arrived at the same conclusion, and he says that when cortical ptosis exists from damage to one side only of the brain cortex the centres for the elevators of the upper lid are not so closely associated as usual. Again, fallacies have doubtless arisen from the fact that all the external ocular muscles, the levator palpebræ included, may be excited to coördinated movements by vigorous stimulation in many parts of the brain cortex; moreover, it is but rarely that one has the opportunity of making a necropsy in a case of cortical ptosis, or if such an opportunity does occur, the lesion is probably so extensive as to render the results in this direction negative.

Landouzy and Grasset advanced the theory that a centre for movement of the upper lid could be localised in the angular gyrus. The lesions, however, in Landouzy's case

Digitized by Google

were, I think, too extensive to admit of the definite conclusions he draws. Lemoine also quotes a case of long-standing ptosis in which, at the post-mortem examination, he found a lesion in the angular gyrus, and he agreed with Landouzy as to the position of the centre. Hirt and others, more recent writers, also hold this opinion. Ferrier thinks that these conclusions are not warranted by experiment. He says, "Some such cases" (that is, of ptosis due to a small lesion in a definite area of the cortex) "have been observed in connexion with diseases of the cortex, and attempts have been made, but not, I think, successfully or in accordance with experimental lesions, to localise this centre in the angular gyrus. If a distinct volitional centre for the levator palpebræ superioris exists in the human brain I think it must be sought for at the base of the first frontal and extending partly into the second frontal convolution of the brain. Here is an area, irritation of which in the brain of the monkey causes elevation of the eyelids." Ferrier found, moreover, in applying stimulation to this area that if the stimulus were very faint elevation of the lids was the only movement that followed. Although movement of the eyelids can be seen on stimulating the angular gyrus the latent period, as pointed out by the same observer, is one-hundredth of a second longer than in the case of stimulation applied to the oculo-motor centre in the frontal lobe. Schäfer and Ferrier both found that when the angular gyrus was destroyed on both sides in the brain of a monkey, no ptosis was produced; and movements of the lids caused by stimulating this area are probably due to association with the frontal region. In one of Ferrier's experiments he extirpated the greater part of the frontal lobe in a monkey; ptosis with some disturbance of ocular movement was the only paralytic effect produced.

De Bono, as a result of the study of clinical cases, came to the conclusion that a cortical centre for the levator palpebræ superioris could be localised in the fore part of the brain. The two cases from which he chiefly drew his conclusions were both in young women affected with ptosis and subject to epileptiform attacks. In the one case the ptosis was congenital, and in the other it was of four years' duration. The epileptiform attacks in both cases began in the arms, and spread sometimes to the face and legs. De Bono thought that the lesion which caused the ptosis was also very probably the focus from which started the convulsions; and upon this he founded his theory that the centre for elevation of the lid must be closely associated with the centre for movement of the arm. Examination of the skull of the patient suffering from congenital ptosis revealed a depression about one finger's width in the zygomo-Rolandic line, 93 mm. from the external auditory meatus and 102 mm. from the orbital margin. This appeared to have resulted from an injury at birth, which was a difficult one, and it was considered by De Bono to be the cause of the ptosis. A study of similar heads showed that the depression corresponded to the anterior central (or ascending frontal) convolution at the junction of the middle with the upper two-fifths. Experiments on living dogs seemed to confirm this observation; and De Bono arrived at the conclusion that a centre for elevation of the lid of the opposite side could be localised in the anterior central convolution rather above the middle in front of the motor centre for the arm and above that for the face. These results of clinical observation are very similar to those arrived at by Ferrier's experiments.

Several cases of ptosis, as a result of blows upon the top of the head, have been reported. Thus Mr. Hulke, in the Reports of the Royal London Ophthalmic Hospital, gives such a case, which he thought was due to direct injury to the cortical centre, but it is more probable that such results are, generally at least, due to a lesion at the base. The following case, however, which is from the notes of a case which was under my own observation, points strongly, I think, to frontal localisation of the cortical centre for the levator of the eyelid.

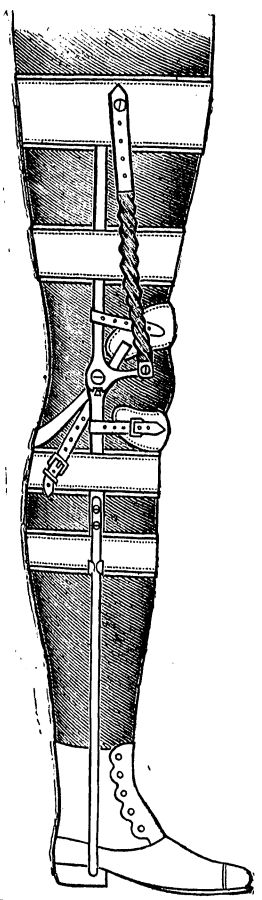
A boy, aged twelve years, was swinging round a giant's stride when the iron wheel and arms on the top of the pole came off and fell, striking him on the top of the head above the right eye. When I first saw him, sixteen hours later, he was semi-conscious and lay quietly with both eyes closed unless irritated. He could, however, open both eyes widely and there was no paralysis of any muscle or group of muscles. On removal of the carbolic compress which had been applied a large spoonful of brain matter was seen protruding from the anterior extremity of a large jagged wound situated in the right frontal region. The wound extended about three inches back from the brow and was about one and a half inches in width, the middle line of the head being about one and a half inches from the upper edge of the wound. Beneath this the skull was crushed in like the broken shell of an egg, making a depression in which two fingers could lie. On giving chloroform and enlarging the wound the fracture in the outer table of bone was seen to reach to the coronal suture, and the fracture of the inner table about half an inch to one inch beyond. The membranes were extensively torn, and the depressed part of the skull was driven into the brain especially in front. Owing to the extensive fracture of the inner table of the skull I had some difficulty in elevating, having to remove three circles of bone with the trephine. About two or three drachms of brain matter, over and above what had escaped before, were lost during the operation chiefly from the posterior end of the wound. The bone removed by the trephine was replaced and the wound was dressed. The patient remained in a semi-conscious condition for twelve days, and then steadily recovered. There was never any sign of meningitis, and no paralysis occurred with the exception of the left eyelid. Here ptosis appeared directly after the operation, and persisted for ten weeks. It was never absolute and gradually passed off. At the end of twelve weeks it had practically disappeared. I saw the boy occasionally during the next five months. The ptosis entirely disappeared, and so far as could be seen there were no permanent evil results from the extensive head injury from which he had suffered.

Noting the position of the fracture and its relation to the coronal suture it is seen that the posterior end of the fracture, from which the brain matter chiefly escaped during the operation, just about reaches the ascending frontal convolution, and that the level is that of the second (or middle) frontal convolution and the sulcus between the first and second convolutions. I believe that in this case the monolateral ptosis was the result of destruction of the cortical centre, probably during the elevation of the depressed bone, and that recovery was due to the function being assumed by the opposite side. I think that one may exclude the possibility of the ptosis being a nuclear paralysis because there was no ptosis to be observed sixteen hours after the accident and before the operation, but immediately after the operation ptosis was observed, which, however, did not increase in severity.

After weighing the evidence I think that the following conclusions are warranted:—1. There is a distinct cortical centre for the elevator of the upper eyelid. 2. This centre is situated in the posterior extremity of the second frontal convolution, extending probably into the first frontal convolution; that is, above and in front of that suggested by De Bono, and rather lower than the position assigned by Ferrier. 3. There is a definite relation between this centre and the levator palpebræ superioris of the opposite side, and destruction causes paralysis, temporary or permanent, of the lid on the opposite side. 4. This cortical centre is distinct from the cortical centre or centres for the other eye muscles; and therefore, as a result of a cortical lesion, ptosis may occur as a solitary paralysis; or on the other hand, in cortical paralysis of the muscles of the eye, the levator may alone escape. It is interesting to note that the blood-supply of this cortical area is double, it being supplied both by the anterior cerebral and the middle cerebral arteries, which may account for the rarity of ptosis from cerebral embolism.

Edinburgh.

FRACTURE OF THE PATELLA.



BY HEATHER BIGG, F.R.C.S. EDIN.

THE immediate result of transverse fracture of the patella is that the tibia is more or less completely severed from its connexion with the extensor muscles of the thigh and the natural object of all treatment must therefore be to reunite this connexion between the two parts with as much strength and completeness as possible so that the powers of the knee joint may be restored to their fullest ability in walking. In the present days o advanced surgery this end is frequently attained by the actual operation of suturing the fragments together. But this is not always admissible and the alternative method of apposing the segments by external

Digitized by Google

means has to be adopted. My object is to show in what manner and by what apparatus not only may the closest junction be attained between the broken segments, but also how, by a graduated system of strain, the newly-laid material of junction may be cultivated into the greatest strength and endurance. Sir Astley Cooper in his "Treatise on Dislocations" lays down the proper laws of treatment in so clear a way that, although since his time the methods may have materially improved, the principles that underlie them remain classic and unchanged. "Confine" (he writes) "the leg quite straight with circular bandages above the knee for five or six weeks. Then a slight passive motion is to be begun and this must be done gently with much circumspection, that the ligament if not firmly united may not give way and the bones recede. If the union be found sufficiently firm to bear it then passive motion is to be employed from day to day until the flexion of the limb be complete. If passive motion be not used it appears that the action of the extensor muscles would never return." He goes on to write that after the passive motion has been duly used the patient should be placed on a high chair and directed to swing his leg in order to ensure under voluntary motion the gradual restoration of the powers of the muscle.

Now if the essentials of treatment be put into sequence they will be found to run as follow: (1) to approximate the fractured segments as completely as possible; (2) to maintain them in undisturbed apposition so that new material may be easily and reposedly laid down; (3) to submit this new material when formed to graduated strain in such a way as to provoke it to the greatest strength; (4) to passively and gradually renew the movements of the knee-joint from complete extension to complete flexion; and (5) to restore the extensor muscles of the thigh to active power and nutrition after their enforced atrophic quiescence. The way in which I have found all these essential conditions most perfectly satisfied is by an apparatus having the construction shown in the accompanying illustration. It consists of two lateral rods extending along each side of the leg; these are jointed at the knee and connected by four metal bands, two encircling the thigh and two the calf. A continuation of the rod on the outer side of the leg reaches to the sole of the foot where it fits into a socket in a bed-shoe if the patient is still recumbent, or a boot when the patient has started walking; this accessory rod is simply to localise the whole apparatus in a precise and fixed position on the leg. The rest of the special mechanism is at the knee. In the first place the joints of the lateral rods are "locked joints"—that is to say, they are made fixed and incapable of any movement at all when the instrument is first put on the extended and quiescent leg; but the lock is so arranged that it can by filing be cut away at will and flexion thereby be gradually introduced until at last the complete right-angle is reached. Next there are at the joints of the rods short levers to which are attached elastic "mock-muscles" with an extensor power fully equivalent to that of the quadriceps. Lastly, there are two semilunar pads for holding the segments of the patella. The lower pad is fastened to the lateral rods by transverse straps, its object being simply to hold the lower segment steady. The upper pad has two sets of straps, one set acting transversely so as to bring the pad directly home over its segment and the other set acting obliquely downwards in such a direction as to bring the upper segment down into apposition with the lower one.

The application of the apparatus is as follows:—At the outset, whilst the patient is still in bed, it is applied in perfect and rigid extension, and whilst the lower segment is steadied by its semilunar pad the upper segment is readily and without difficulty brought down and retained in proper apposition by its semilunar pad. When the new tissue of juncture between the segments is estimated (generally in about six weeks) to be sufficiently formed and to be capable of some incipient strain then the patient begins to walk with a stick, the instrument remaining rigid for a further week or so. Then the "locked joint" at the knee is released by amounts of about five degrees at a time every few days until the complete right angle of flexion is attained. All this while the extensor "mock muscles" are kept at their fullest tension, their object being to relieve the quadriceps of any work whatever. In every-day walking with the knee-joint mobile it is the quadriceps that flings the leg forward; the "mock muscles" of the apparatus do the same thing artificially and the quadriceps consequently has no need to come into action at all and therefore does not pull on the upper fragment of the patella, which is thus left undisturbed to follow its lower segment in apposition. When, however, flexion has been permitted to reach the right-angle then the "mock muscles" are loosened little by little and the quadriceps gradually begins to pull on the mended patella until it is allowed to do so in its full strength. Finally, the lower semilunar pad is removed whilst the upper one is slightly loosened but is left as a necessary safeguard for a few weeks longer after which the whole apparatus can be discarded.

The feature of this particular treatment is that not only are the segments safely held in apposition, but the reunited bone is submitted by controllable graduations to movement and to strain and the new tissue of union is thereby provoked into attaining perfect strength; for all tissues strengthen under graduated provocation and the fact is perhaps better illustrated in fractured patella than in any other instance. I have notes of close on 300 cases satisfactorily dealt with by this method and it may be added in conclusion that with some modifications of detail it is equally applicable to ruptured quadriceps and to ruptured ligamentum patellæ.

Wimpole-street, W.

REMARKS ON THE MORTALITY FROM CANCER.

BY W. ROGER WILLIAMS, F.R.C.S. ENG.

YEAR after year the Registrar-General's reports keep on repeating that the cancer death-rate is the "highest on record," and this has been going on continually for more than half a century. Yet, so far as I can see, no effect has been produced on the great mass of professional and lay opinion by these constantly reiterated warnings. We often hear of efforts being made to stay the progress of diseases like typhoid fever, small-pox, and tuberculosis—all of which are, and for many years have been, steadily declining; so that in the future we need only improve a little on what we have done in the past to ensure their eventual extinction. But with regard to cancer the case is very different, for the conditions of life are such that if no effort is made to check the progress of this disease it will ere long be as lethal as all the above-mentioned maladies combined. That this is no imaginative statement the subjoined table shows. Yet I have no hesitation in declaring my belief that there need be no more difficulty in mitigating the prevalence of cancer—and perhaps even in eventually extinguishing the disease altogether—than there is in the case of the maladies mentioned above. I believe that the tendency to cancer may be increased by unsuitable modes of living and *vice versâ*. We must therefore seek out those conditions which favour its development; and by avoiding them we shall be able to effect our object. In my opinion it is only by progress along such lines that the cure of cancer is ever likely to be effected.

In this connexion such influences as are comprised under the terms alimentation and domestication seem to

Digitized by Google

me to be of paramount importance. Probably no single factor is more potent in determining the outbreak of cancer in the predisposed than high feeding. There can be no doubt that the greed for food manifested by modern communities is altogether out of proportion to their present requirements. Many indications point to the gluttonous consumption of meat which is such a characteristic feature of this age as likely to be especially harmful in this respect. Statistics show that the consumption of meat has for many years been increasing by leaps and bounds till it has now reached the amazing total of 131 lb. per head per year, which is more than double what it was half a century ago when the conditions of life were more compatible with high feeding. When excessive quantities of such highly stimulating forms of nutriment are ingested by persons whose cellular metabolism is defective it seems probable that there may thus be excited in those parts of the body where vital processes are still active such excessive and disorderly cellular proliferation as may eventuate in cancer. No doubt other factors coöperate and among these I should be especially inclined to name deficient exercise and probably, also, deficiency in fresh vegetable food.

In 1840 cancer caused 2786 deaths, the proportion being 1 in 5646 of the total population and 1 in 129 of the total mortality, or 177 per million living. In 1896 the deaths due to it numbered 23,521, or 1 in 1306 of the total population and 1 in 22 of the total mortality, or 764 per million living. Thus the proportionate mortality from cancer now is four and a half times greater than it was half a century ago. In this respect its position is unique, for no other disease can show anything like such an immense increase.

In illustration of this subject I have compiled the following table:—

TABLE I.—*Showing the Prevalence of Cancer and its Increase in England and Wales since 1840.*

Year.	Total population.	Total deaths.	Cancer deaths.	Cancer death-rate per million living.	Proportion to population.	Proportion to total deaths.
1840	15,730,813	359,637	2,786	177	1 to 5,646	1 to 129
1850	17,773,324	368,995	4,966	279	1 to 3,579	1 to 74
1855	18,829,000	426,646	6,016	319	1 to 3,129	1 to 70
1860	19,902,713	422,721	6,827	343	1 to 2,915	1 to 62
1865	21,145,151	490,909	7,922	372	1 to 2,670	1 to 62
1870	22,501,316	515,329	9,530	424	1 to 2,361	1 to 54
1875	24,045,385	546,453	11,336	471	1 to 2,121	1 to 48
1880	25,714,288	528,624	13,210	502	1 to 1,946	1 to 40
1881	25,974,439	491,937	13,542	520	1 to 1,918	1 to 36
1882	26,413,861	516,654	14,057	532	1 to 1,879	1 to 36
1883	26,770,744	522,997	14,614	546	1 to 1,763	1 to 35
1884	27,132,449	530,828	15,192	559	1 to 1,786	1 to 35
1885	27,490,041	522,750	15,560	566	1 to 1,767	1 to 33
1886	27,870,586	537,276	16,243	583	1 to 1,715	1 to 33
1887	28,247,151	530,758	17,113	606	1 to 1,650	1 to 31
1888	28,628,804	510,971	17,506	610	1 to 1,635	1 to 29
1889	29,015,613	518,353	18,654	643	1 to 1,555	1 to 27
1890	28,762,287	562,248	19,433	676	1 to 1,480	1 to 28
1891	29,081,047	587,925	20,117	692	1 to 1,445	1 to 29
1892	29,405,054	559,684	20,353	690	1 to 1,445	1 to 27
1893	29,731,100	569,958	21,135	711	1 to 1,407	1 to 27
1894	30,060,763	498,327	21,422	713	1 to 1,403	1 to 23
1895	30,383,047	568,997	22,945	755	1 to 1,324	1 to 24
1896	30,717,355	526,722	23,521	764	1 to 1,306	1 to 22

Mere increase of population will not account for this continuously progressive augmentation of the cancer death-rate, as is evident from the fact that its rate of increase has proportionally been much in excess of this, and there is far too much uniformity in the variations of the increments of increase in the long succession of years to warrant its being ascribed to improved diagnosis or other casual error. Moreover, I have ascertained that the increase has not been confined to one or a few parts of the body, but that it has involved them all—on the whole without any considerable disturbance of the normal proportionate localisation ratios.

The attempt to explain the increasing cancer mortality as due to the average age of the population having advanced and the consequent liability to greater numbers of cases of cancer will not bear critical examination, for the saving of life in modern times has been mainly confined to early years. The death-rates of males over thirty-five years and of females over forty-five years have either remained stationary or increased, while the number of those who attain old age has decreased. This heavy mortality at post-meridian ages is no doubt largely due to the survival in augmented numbers of weakly lives artificially prolonged by improved conditions of existence, but not more than a small fraction of the increased cancer mortality can be thus accounted for. Besides, it is a mistake to assume that increased cancer mortality is a necessary corollary of the survival of augmented numbers to the cancer age; for instance, the average age of the population of Ireland is much higher than that of the population of either England or Scotland, owing to the large number of elderly people left behind after the younger ones have emigrated, yet the cancer mortality of Ireland is much less than that of either England or Scotland. In most civilised countries where statistical records have been kept similar increases, although less pronounced, have been observed.

A remarkable fact about the increasing cancer mortality is that it has affected males to a much greater extent than females. The following table illustrates this.

TABLE II.—*Showing the Relative Increase of Cancer among Males and Females.*

Period.	Cancer death-rate.		Sex ratio.
	Male.	Female.	
1851–60	195	434	1 to 2·2
1861–70	244	523	1 to 2·1
1871–80	315	622	1 to 1·9
1881–90	430	739	1 to 1·7
1891–95	47	868	1 to 1·6
1896	618	901	1 to 1·4

Thus while the cancer mortality for males from 1851 to 1890 has increased 167 per cent., the increase for females has been but 91 per cent. It seems to me probable that this undue incidence of the increasing cancer mortality in males may be ascribed to the fact that of late, as the result of urbanisation, the conditions of life for men have come to resemble more closely those for women than heretofore. Excess of food, with want of proper exercise and changed surroundings, are, I think, its chief causative agents.

Clifton.

SOME NEW FEATURES OF THE ACCESSORY CAVITIES OF THE NOSE.

BY ROBERT H. CRAIG, M.D.

IN the following notes I have briefly indicated certain features of the accessory cavities of the nose which have hitherto not received attention.

The growth of the antrum of Highmore depends upon the development of the superior maxillary bone. The deeper the canine fossa the smaller the antrum, and it is interesting to note that the canine fossæ of the white race are smaller than those of the negro. As a rule, elderly people have deeper canine fossæ than young adults and individuals with projecting canines have also deep fossæ. The size of the cavity depends greatly on the thickness of the walls. Large cavities have thin walls; on the other hand, the walls of a small antrum are always thick, the difference in size depending upon the amount of absorption during development. These anatomical facts have a special clinical bearing, for in inflammation of the mucous membrane of a large cavity with thin walls the inflammatory products press more closely on the branches of the trigeminus and this accounts for the frequent symptoms of referred pain in such cases. The antrum is often divided into two or more

Digitized by Google

parts by bony partitions, as shown by Zuckerkandl's sections. According to the teachings of Tandler the dimensions of the cavity may be obtained by the three following external measurements: (1) *the heighth* from the infra-orbital floor to the alveolar process; (2) *the breadth* from the pyriform aperture to the zygomatic process, deducting from 1 to 2 millimetres to allow for tissue; and (3) *the depth* from the external angular process to the level of the upper part of the canine fossa. The normal opening of the maxillary antrum is situated in the posterior part of the hiatus semilunaris under the anterior end of the middle turbinated bone. According to Chiari, Hajek, and other authorities an accessory opening is found in every fifth case in the middle meatus posterior to and deeper than the normal aperture.

The frontal cavity.—The size of the cavity is inconstant; its upper limit is judged by the height of the superciliary ridge, the lower by the incisura orbitalis or fronto-maxillary suture; its outer boundary by a line drawn downwards from the supra-orbital notch. The opening of the cavity is situated in its most dependent part and leads into the naso-frontal duct.

The ethmoidal labyrinth.—According to the teaching of Hajek this is developed from four basal plates (sometimes one or more supernumerary plates are found between the middle and superior turbinal). The plates are: (1) the unciform; (2) the bulla; (3) the middle turbinated; and (4) the superior turbinated. Most of the anomalies which are so frequently found in connexion with this cavity are caused by variations in the evolution of these plates. Between the first and imperfectly developed unciform process and the bulla is the hiatus semilunaris, between the second and third plates the anterior ethmoidal cells are situated, between the third and fourth the middle ethmoidal cells are found, and behind the fourth plate the posterior cells. According to the latest views the relation of the anterior ethmoidal cells to the infundibulum is as follows. The cells are usually found only posterior to the hiatus semilunaris, but in some cases the whole hiatus is enveloped in the anterior labyrinth—a fact of great surgical importance. The fissures between the plates are known as inter-turbinal ways and every inter-turbinal way may have appendages supplied with ducts. Thus the hiatus semilunaris is to be regarded as an inter-turbinal way and the cells which lead from it as infundibular cells. Each ethmoidal cell usually communicates with the fissure with which it is connected and if the cells do not open directly into their respective fissures they open into other cells which do open direct; for example, if there are five cells in the anterior part of the labyrinth and only two open into one of the fissures the other three communicate with the two which open direct.

The relationship of the ethmoidal cells to the frontal cavity.—It is found that the plate of the bulla ethmoidalis separates the frontal cavity from the ethmoidal labyrinth and the size of the former cavity is more or less dependent upon the position of the bulla. Hajek's prefrontal cavity is placed between the anterior ethmoidal plate and the frontal sinus and is caused by a backward deviation of the plate of the bulla. The bulla is subject to anomalies, thus: 1. In some cases the bulla does not reach as high as the criboriform plate and the frontal cavity communicates with the anterior ethmoidal cells. 2. The median plate of the bulla may be defective and the whole anterior ethmoidal labyrinth then communicates with the frontal sinus. An ethmoidal cell is often found in the anterior end of the middle turbinal but this must not be regarded as an anomaly for it is only isolated from the rest of the labyrinth as described by P. Heymann. The duct of this cell frequently becomes occluded and gives rise to a prominent swelling on the anterior end of the middle turbinal. The most constant opening of the anterior ethmoidal cells is situated between the bulla and the anterior insertion of the middle turbinated bone, that of the middle farther back, behind and above the bulla, while the posterior opening is in the recessus spheno-ethmoidalis.

The sphenoidal cavity.—The size of the cavity is inconstant and its lateral walls are sometimes defective owing to an osteo-porosis. In such cases mucous membrane alone separates the cavity from the meninges. The size of the opening varies, but it is always situated in the anterior wall, the distance of the aperture from the anterior nasal spine being about from 8½ to 9 centimetres in the male and from 7½ to 8 centimetres in the female.

MIDDLESEX HOSPITAL.

A CASE OF IMPERFORATE HYMEN; RETAINED MENSES; HÆMATOCELE; OPERATION; RECOVERY.

(Under the care of Dr. PASTEUR and Mr. ANDREW CLARK.)

IN different cases of imperforate hymen different portions of the genital canal may be dilated; in the vast majority of the cases the uterus is much distended; in others the Fallopian tubes, and in others again the vagina is the part most affected. When the uterus is dilated the tubes are often enlarged also, and this accounts for the regurgitation along them of the menstrual fluid which is very liable to occur. It is very rarely that abdominal section is required for retained menses, and very few cases are on record. Alexandroff[1] recommends that laparotomy should be performed if dilatation of the Fallopian tubes is diagnosed, and especially if one of the tubes has ruptured. A case in many respects similar to the one recorded below was reported by Webster.[2] It was found necessary to remove the distended left tube, but unfortunately the patient died six weeks later from septic peritonitis. In cases of imperforate hymen it cannot be rare for the retained blood to pass backwards into the peritoneal cavity and it is probable that in most cases no very serious results follow, though it is possible that the pelvic hæmatocele resulting may give rise to peritoneal adhesions, but when the hymen has been incised an easy passage is left for the entrance of septic organisms and then the effused blood will greatly facilitate their development.

A girl, aged fifteen years, well nourished but anæmic, was admitted into the Middlesex Hospital on April 27th of the present year under the care of Dr. Pasteur on account of abdominal pain and swelling. She had had a similar attack but not so severe about a year previously which cleared up after a few days' rest in bed, but beyond this she had always enjoyed excellent health and did not remember having been laid up, except with scarlet fever in 1896, from which she recovered perfectly. She had never menstruated nor had she had any indication of the commencement of that function. The present illness began with severe headache on April 23rd—that is, four days before her admission to the hospital. She passed a very restless night and had cramps in her abdomen and legs. On the next day she had pains in her back and the lower part of her abdomen and lost her appetite. The pain in her back got better, but that in the abdomen got so much worse that her mother took her to the hospital. The bowels had been regular. On admission her organs were normal. The pulse was 108 and the temperature was 100·2° F. She complained only of pain in the abdomen and the following is the note of its condition: "There is no uniform distension of the abdomen, but between the umbilicus and the right iliac crest there is a marked swelling with its edges more or less well defined and with a surface area about four inches across. It is resistant on palpation, dull on percussion and intensely tender." The condition of the patient on the next day was much the same; she had not been sick, her bowels had not been opened, she had no appetite, and her tongue was coated. The pulse was 100 and the temperature was 99° at 6 A.M. and 99·8° at midday. The abdomen was decidedly more tender, especially at the outer part of the swelling and by rectal examination a tumour could be felt pressing on the bowel. The next day the condition was practically the same. The temperature on the previous night had been 100·4° and the patient had been and still was very

[2] American Journal of Obstetrics, September, 1895.

Digitized by Google

restless. Though the symptoms were not altogether those of appendicitis this was believed to be what she was suffering from and it was thought that an operation was desirable. Accordingly about 4 o'clock on the 29th the patient was anæsthetised, gas and ether being employed, and an incision was made over the most tender part of the tumour, which happened to be the usual spot chosen for appendectomy. On opening the peritoneal cavity a large quantity of dark-coloured fluid and clotted blood escaped from the wound. The finger was introduced and a soft tumour of about the size of a fœtal head was felt. This was drawn out of the wound and proved to be an enlarged ovary and Fallopian tube. The fimbriated extremity of the latter was congested and patulous and dark-coloured blood was issuing from it. Further manipulation showed that the uterus was much enlarged and that the left Fallopian tube was also much distended and the ovary considerably above the natural size. The vulval orifice was now examined and it was found to be closed, so the abdominal wound having been carefully covered the patient was put in the lithotomy position in order that the condition of the vagina could be properly made out, and it was found to be simply a case of imperforate hymen not bulging forward as usual in the least. An incision was made into it and a quantity of dark fluid blood escaped. This was found to have distended the vagina laterally as well as the uterine cavity. These were irrigated with a perchloride of mercury solution and a cyanide gauze plug was loosely introduced. The patient was then returned to the original position, the abdominal wound was sponged dry, the wall was sewn up with fine silk, layer by layer, a cyanide gauze dressing was applied, and the patient was returned to bed. Hot vaginal douches were ordered to be made every four hours and in the intervals the vagina was to be kept loosely plugged with iodoform gauze. On the next day the patient appeared to be comfortable and was in no pain. The only things to note were that the temperature was 100·2° and the pulse was 120, and the night temperature and pulse remained at this till the fourth day after the operation, when they came down to 99·2° and 102 respectively, below which they rarely went while the patient was in the hospital. The dressings were taken off on May 6th, when, the wound being quite closed, the stitches were removed and a collodion dressing was put on. There is nothing else to note about the case, there was no cause for any anxiety, and the difficulty was to keep the girl in bed. She was not, however, allowed to get up until the 27th, a month after the operation, and was sent to the convalescent home on June 2nd. She was again seen on her return from the convalescent home on the 27th and expressed herself as being quite well, but there had been no sign of another period. A vaginal examination was made with the patient under the influence of an anæsthetic and the aperture in the hymen, much thickened and very dense, was dilated. The pelvic organs were normal.

Remarks by Mr. ANDREW CLARK.—There are two points about the above case which induce me to put it on record. The first point is the rarity of the condition. An imperforate hymen is comparatively common, but in the majority of instances it shows itself by protrusion of the membrane from the vulva, the swelling getting larger and larger with each menstrual period, dilating the vagina to an enormous extent and pushing the uterus up into the abdomen. Sometimes the uterus becomes distended also, as happened in a slight degree in this case, but here, in addition to the distended vagina and uterus, there were dilatation of the right Fallopian tube and a back flow of the fluid into the peritoneal cavity, a hæmatocele forming there. This was probably due to the thickness and absence of elasticity in the hymen. The other point is the error in the diagnosis of the condition. I must confess that the idea of an imperforate hymen being the cause of the trouble never entered my head until I saw the blood, and though the history was perhaps not altogether typical of appendix abscess, still the one previous attack, the position of the swelling and its extreme tenderness, together with the age and appearance of the patient, and the absence of any history of monthly trouble, would, I venture to think, suggest to few surgeons the propriety of a vaginal examination, a rectal examination having already been made. Then, again, the importance of early operation and its practical safety and the risk attendant on the presence of a localised collection of pus in such a position make one resort to operation with little hesitation, for if there is a class of case in which the surgeon should act on the principle of "when in doubt, operate," it is that of appendix abscess. Had I looked at the vulva first no doubt I should have been contented with making a free opening through the hymen, but as the case has turned out, I think that what was done was best, for I doubt if the quantity of effused blood would have been absorbed anything like so quickly, and I do not think that the girl would have been convalescent and able to enjoy life again in so short a time as two months.

LEEDS GENERAL INFIRMARY.

A CASE OF INTUSSUSCEPTION; OPERATION; RECOVERY.

(Under the care of Mr. W. H. BROWN.)

WE have pointed out on several recent occasions in commenting on cases of intussusception that the tendency during the last two or three years has been to operate at an earlier period than formerly. At one time inflation or injection always preceded laparotomy, and the necessary shock of the operation often proved fatal to the child already much exhausted by the unsuccessful preliminary attempts. The statistics of these cases of "secondary" laparotomy are perfectly useless for estimating the value of operation in intussusception, but with the recent increase in the proportion of cases treated at once by laparotomy the percentage of recoveries has increased. It would be very desirable if all cases of intussusception treated by operation could be recorded and then the statistics would be of more value than at present. It cannot be too much insisted on that in a large proportion of the cases of this disease no inflation or injection could reduce the intussuscepted bowel. Mr Brown's case reported below is a good instance of this; the grasp of the ensheathing layer of bowel was so tight that even reduction by manipulation was difficult. In such cases as these inflation can only do harm and operation holds out the sole hope of a successful result. For the notes of the case we are indebted to Mr. E. J. A. Dodd, house surgeon.

A boy, aged three years, was admitted into the Leeds General Infirmary on March 31st, 1898, suffering from pain in the abdomen and tenesmus. The patient had been quite well until two days before admission, when he was seized with pain in the abdomen. He had vomited on several occasions and had passed blood *per rectum*. On admission the abdomen was found to be slightly distended and on palpation an elongated swelling could be felt in the region of the ascending and transverse colon. There was some tenderness of the abdomen. The child was in fairly good condition, the pulse was rapid but good, and as before admission attempts at reduction by means of injections had been made an operation was decided upon.

A couple of hours after the admission of the patient ether was administered and the abdomen was opened in the middle line below the umbilicus by an incision 4 in. long. On putting the hand into the abdomen an intussusception was found extending from the cæcum to the splenic flexure of the colon. The apex of the intussusception at the splenic flexure was then brought outside the abdomen and by means of gentle pressure with the finger and thumb the greater part of it was easily reduced, the bowel being returned to the abdomen. The intussusception in the last few inches was found to be folded upon itself in its longitudinal axis and had the appearance of a double intussusception. The bowel was brought further out of the abdomen and was with difficulty reduced by means of manipulation. This portion of the bowel was found to be very much swollen, especially where the two surfaces had been in contact, and was very much inflamed, but the serous coat had not lost its lustre. The wound was then washed over with carbolic lotion, the abdomen was closed, and a dry dressing was applied. The after treatment was simple. A small dose of nepenthe was given on the night after the operation, but it was not repeated. The wound was dressed on the seventh day and healed by the first intention. The bowels were opened on the sixth day by a simple enema and were subsequently kept open by small doses of castor oil. The patient was discharged on April 30th. He was seen two months later and was then quite well.

Remarks by Mr. BROWN.—In a recent number of THE LANCET there appeared notes of two cases of

Digitized by Google

intussusception treated by early operation; as the details were very similar I venture to add the above case to the scanty records of successes. If more evidence in favour of early operation be needful I venture to think it would be forthcoming if surgeons were less reticent in publishing isolated cases. The condition of the bowel at the initial point of invagination showed that a few hours' more delay would have resulted in sloughing, for the swollen patches which were in contact were very suggestive of destructive pressure. I have only once seen an intussusception undergo spontaneous cure and this after weeks of great suffering. Unfortunately operation is resorted to only after a prolonged trial of palliative measures has failed. I think it would be a good rule to regard cases of intussusception in the light of strangulated herniæ and treat accordingly. If the risk of abdominal section is great the risk of leaving invaginated bowel is greater. I have on many occasions had to operate only to find sloughing intestine, and then the necessary manipulations, either to restore the continuity of the canal or the formation of the artificial anus, call for a prolongation of the operation which is rarely compatible with life.

Reviews and Notices of Books.

Anatomical Atlas of Obstetric Diagnosis and Treatment. By OSCAR SCHAEFFER, M.D. With 145 Illustrations. London: Baillière, Tindall and Cox. 1897. Crown 8vo. Pp. 230. Price 12*s.* 6*d.*

Atlas and Essentials of Gynecology. By OSCAR SCHAEFFER, M.D. With 64 Plates and 54 Woodcuts. London: Baillière, Tindall and Cox. 1897. Crown 8vo. Pp. 288. Price 15*s.*

IT may well be a matter for discussion whether an author is wise in attempting to combine an atlas with a text-book as has been done in these two books. One or other part must inevitably suffer and, although Dr. Schaeffer might perhaps say that his letter-press is mainly secondary to the plates, yet since he has given us more than a mere description of the plates we must regard the second part of these two works as of the nature of a text-book.

The "Anatomical Atlas of Obstetric Diagnosis and Treatment" consists of two parts. The first part is composed of some 145 figures, a large number coloured, illustrating anatomical conditions in connexion with pregnancy, types of various forms of contracted pelvis, and some of the pathological complications of pregnancy and labour. The drawings are of very unequal merit and interest and are very largely taken from preparations in the Munich Gynæcological Clinic, with which the author was for some time connected. They give a clear idea of the conditions which they are intended to represent, but cannot be regarded from the artistic point of view as wholly successful, nor indeed are they all strictly accurate. Fig. 110, Tamponade of the Bleeding Uterus, after Dührssen, would give a student an entirely erroneous impression as to how to plug a uterus for post-partum hæmorrhage. The most essential feature in the operation is to plug the uterus from above down, and great care should be taken to plug the upper part of the uterine cavity. In the figure mentioned—described as an original drawing after Dührssen's direction—the tampon is shown filling only the lower half of the uterine cavity, leaving the upper half entirely empty. A reference to Dührssen's own description of the operation in his "Geburtshülfliches Vademecum" will show that he particularly directs that the tampon should be carried up to the fundus of the uterus and that the uterine cavity should be completely packed from above down. The illustrations of contracted pelvis, of which there is a very complete series, would have been of much greater value had they all been drawn to scale. Fig. 107, representing a rupture of the fundus of the uterus from the Munich Clinic, is of very great interest, although, unfortunately, no history is available. The second half of the book consists mainly of a description of the conditions which are illustrated by the plates. Occupying as it does only about 180 pages it is of necessity very greatly condensed. For this reason some of the paragraphs on treatment can hardly be regarded as a safe guide to the student. As an illustration of this we may turn to the section giving the treatment of a case of accidental hæmorrhage. This is summarised as follows: "If the cervical canal is somewhat dilated, rapid delivery, perhaps by accouchement force, or by Cæsarean section in atony of the uterus after failure of hot injections, tamponade, and ergotin," no mention being made of rupture of the membranes and no details being given as to what is the correct treatment if the cervical canal be not somewhat dilated.

The "Atlas and Essentials of Gynecology" also consists of two parts, the first half of the book being made up of some 170 coloured illustrations, and the second half of letter-press further illustrated by woodcuts. The plates illustrating diseases of the external genitalia and of the cervix uteri are of considerable value and they are supplemented by drawings of some of the microscopical appearances met with in the various conditions figured. There is a large number of schematic diagrams illustrating the various displacements of the uterus and the methods of replacement, and these, no doubt, would be of value from a teaching point of view. Carcinoma of the cervix and of the body of the uterus is illustrated by a number of original water-colour drawings after von Winckel and from preparations in the Munich Clinic. The second half of the book consists of 5 parts; the first is concerned with Malformations and Arrests of Development, the second with Changes in Shape and Position of the Pelvic Organs, the third with Inflammation, the fourth with Injuries, and the fifth with Neoplasms. This portion of the work will be useful in helping the student to recall the most important facts connected with gynæcology, but it cannot be considered as complete, and like the second part of the Atlas of Obstetrics it suffers from the amount of condensation which has been found necessary.

These two books do great credit to Dr. Schaeffer's industry and observation, but at the same time we cannot but think that the result would have been of much greater value had the author been content to bring out either a pure atlas or a pure text-book, since in their present form the works are not so complete or useful as they might have been.

De l'Exploration externe en Obstétrique. (*External Examination in Obstetrics.*) Par Professor A. PINARD. Paris: G. Steinheil. 1897.

TEACHERS of obstetric medicine in this country have not been slow to appreciate the great value of abdominal palpation in the practice of midwifery, but in spite of this fact it is still a difficult matter to get students to recognise its great importance and to persuade them to bestow upon it the amount of practice necessary to enable them to acquire any degree of proficiency in its performance. This paper of Professor Pinard, read before the International Medical Congress held at Moscow in 1897, is an authoritative statement as to the possibilities and limitations of abdominal palpation and may be read by all engaged in midwifery practice with the greatest profit. It is not possible for all to become so expert as the author, but he very clearly states what may and what may not be felt if students will but bestow upon this valuable method of examination the requisite amount of practice. In considering the diagnosis by the abdomen of the existence of pregnancy and of its age Professor Pinard calls attention to the fact that after the third month of pregnancy the uterus is more an abdominal than a pelvic organ. With regard to the

Digitized by Google

size of the uterus at the various months of pregnancy he states most explicitly that he has never seen a uterus the fundus of which did not reach above the umbilicus at the fifth month — this we would commend to the attention of some of the authors of English text-books of midwifery, in which the most erroneous statements are to be found as to the height of the fundus of the uterus at the various months of pregnancy. Professor Pinard points out that not only can normal pregnancy be determined by abdominal examination, but also that most of the complications of pregnancy, such as the presence of tumours, hydramnios, hydrocephalus, or hydatidiform mole, can only be diagnosed by this method of examination in the majority of cases. In the same way it is possible to diagnose most cases of multiple pregnancy and of death of the fœtus and to determine the relation between the size of the child's head and the size of the pelvis. He also shows the value of this method in confirming the diagnosis of extra-uterine gestation, but he does not believe that the position of the placenta *in utero* can be determined in any but a very small percentage of cases. During labour abdominal palpation must yield in importance to vaginal examination, and since the diagnosis of prolapse of the cord, of tumours of the pelvis, and of the necessity for rupture of the membranes cannot be determined by the abdomen vaginal examination can never be entirely dispensed with. Appended to the paper are notes of cases of multiple pregnancies, hydramnios, hydrocephalus, &c., in which abdominal examination enabled a correct diagnosis to be made.

LIBRARY TABLE.

Physiologie. Travaux du Laboratoire de M. CHARLES RICHET. Tome iv. Appareils Glandulaires; Nerfs et Muscles; Séro-thérapie; Chloroforme. Avec 57 figures dans le texte. Paris: Félix Alcan. 1898. Price 12 francs.—This volume, which is the fourth of the series, contains fifteen memoirs of which the authors are MM. C. Richet, P. Langlois, C. Beretta, Jotey-Ko, A. Chassevant, J. Héricourt, Saint Hilaire, André Broca, Carvallo, Pachon, Bardier, Athanasiu, and E. Vidal. These articles deal with various subjects of current interest and we propose to supply our readers with an abstract of the more important.

Sir Thomas Browne and his Religio Medici: an Appreciation. By ALEXANDER WHYTE, D.D. London and Edinburgh: Oliphant, Anderson and Ferrier. 1898. Price 2*s.*—The dedication of this little book sufficiently explains its scope and the occasion of its being written. "Dedicated to Sir Thomas Grainger Stewart, President of the British Medical Association, at whose request this appreciation was delivered as the Inaugural Discourse at the opening meeting of the Association in St. Giles's Cathedral on the 26th July, 1898, in great good-will and love by Alexander Whyte." Dr. Whyte thinks the Religio Medici to be Browne's best book, and that the others rank according to their affinity or otherwise with it. It is certainly the most important of his works and the one in which we hear most of the man himself, but to some minds there is a nameless, indefinable charm about the Urn Burial greater than anything in the Religio Medici. Dr. Whyte gives us a just and worthy appreciation of the noble character of Sir Thomas Browne.

Egyptian (Arabic) Self-taught. By C. A. THIMM, F.R.G.S. Second edition. London: E. Marlborough and Co. 1898. Pp. 70. Price 2*s.*—The principal feature of this little book is a very copious vocabulary of words and phrases requisite for travellers in Egypt and the fact of its being now in the second edition shows that it supplies a want. The Egyptian equivalents of the English words are expressed phonetically in ordinary English characters and not in Arabic letters, an arrangement which spares learners the perplexity of reading Arabic characters from right to left. A vocabulary, to be useful, must always give the English pronunciation, for Arabic words are usually written without vowels, as is done in English shorthand; but those who have mastered the alphabet are often helped by having the Arabic characters as well as the pronunciation, an arrangement adopted to some extent in the companion volume, "Arabic Self-taught," published by Messrs. Marlborough.

Annual Report on Meteorological Observations in the Straits Settlements for the Year 1897. By MAX F. SIMON, M.D., Principal Civil Medical Officer. Singapore: The Government Printing Office. 1898. — The greater part of this report consists of 71 pages of tabulated observations made at Singapore, Penang, Province Wellesley, and Malacca. For Singapore the figures show that the barometric extremes were 30·079 in. and 29·739 in., the mean height for the year being 29·89 in. The extremes of air temperature (Fahrenheit) were 92° and 69°, the mean for the year being 80°. The extremes of atmospheric humidity were 98 per cent. and 52 per cent., the mean for the year being 80 per cent. At the Kandang Kerbau Hospital Observatory the total rainfall was 103 in.; the greatest fall in twenty-four hours was 4·93 in. on Feb. 17th.

Bacillus Graminearum. By Dr. GIOVANNI MONTANO. Melfi: Giuseppe Grieco. 1898. Pp. 20.—In some parts of Southern Italy it is well known to the peasantry that if certain kinds of reed are cut, piled up, and left for a time, the opening or removal of these heaps generally causes great irritation of the skin of the workers. Dr. Giovanni Montano, of Lavello, an inland place about fifteen miles from Naples, has studied this subject and has published his results in the present pamphlet as well as in some previous treatises. The reeds in question are Arundo donax, Phragmitis vulgaris, and Calamogrostis epigeyos. When they are piled together until they become mouldy and dry there is an abundant production of a whitish-pink, very fine powder, consisting of spores and filaments of various species of hyphomycetes and schizomycetes, together with numerous spores of dendrochium microsorum containing colonies of a bacillus 5–6 μ in length and 1–2 μ in breadth, which Dr. Montano has called bacillus graminearum. The ill effects produced by these reeds are a violent smarting of the skin, which may even be described as an intolerable burning, cutaneous œdema, and eruption of papules, vesicles, pustules, and bullæ. The lymphatic glands, chiefly those of the neck and groins, are enlarged, the air passages may be seriously involved, and the temperature may reach from 38° to 40° C. (from 100·4° to 104° F.). The symptoms pass off entirely in from six to eighteen days. The same bacillus as that which was found in the powder on the reeds was to be seen in the contents of the vesicles on the skin of the patients.

Rhodes's Steamship Guide. Edited by THOMAS RHODES. London: George Philip and Son. Price 5*s.*—To all those who go "down to the sea in ships" much useful information is available in this book, which is well illustrated with maps, pictures of the better known "ocean greyhounds," portraits of the heads of the leading steamship companies, and coloured plates showing the flags of the various liners, code signals, &c. In addition there is an alphabetical directory of passenger steamers, giving interesting details concerning each; and also a well-written account in non-technical language of the marine steam-engine, placing the uninitiated in possession of some solid facts and figures. We learn, for instance, that a steamer using from 28,000 to 30,000 horse-power converts about half a million pints of water into steam every hour and that only 6 or 7 per cent. of the heat energy of the coal consumed is utilised in the actual forward movement of the ship. There

Digitized by Google

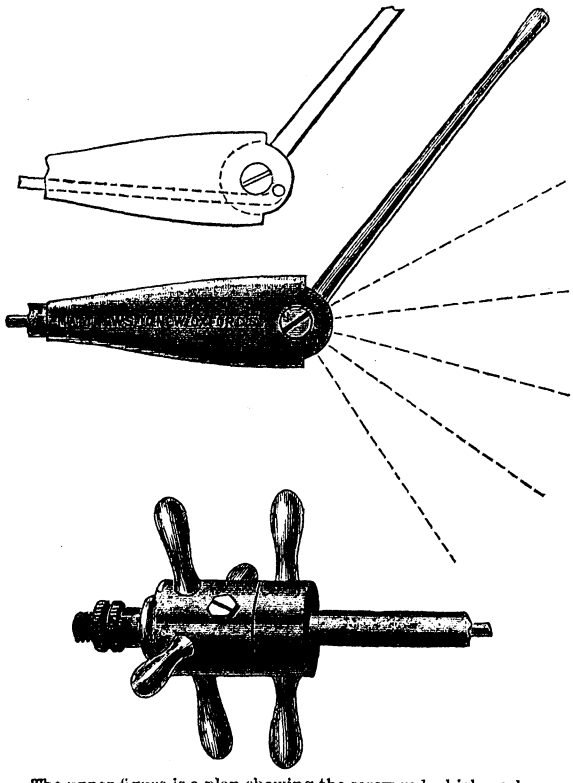
is much that is valuable alike to the traveller, the merchant, and the exporter, and in calling his book the "Bradshaw of the Ocean" the editor is probably not claiming too much.

My Home, and Household Companion. By J. W. JARVIS and W. J. WOODS. London: Simpkin, Marshall and Co., Stationers' Hall Court, E.C. Price 2*s.* paper cover; 3*s.* limp cloth.—There are probably but very few householders who have any reliable idea of the value of their home. When the question of insurance against fire arises some sum is usually guessed at, and, thanks to the infrequency of the event itself, the public generally are satisfied with their haphazard calculations. But when the unlooked-for calamity arises and an inventory of the goods destroyed has to be provided to satisfy the requirements of the fire insurance companies, then the average householder, after laboriously compiling a list of his household furniture, &c. (in which he is tolerably certain to have omitted not a few items), is generally confronted with the fact that the total of his loss exceeds his insurance, and he expresses his surprise that his home was worth so much. "My Home, and Household Companion" is just the book to put these matters right, and it consists of a number of pages ruled off ready for filling in, showing the cost, the date at which acquired, &c., of the goods in each room in the house, not the least valuable part of the book being the detailed inventory of the articles in the various rooms, passages, &c., and the systematic manner in which they are treated. There are, in addition, some useful notes on fire, burglary, life, and accident, insurances, and on wills and death in the house, each containing something which is not generally known. For instance, with regard to fire insurance it appears that, unless specially detailed in the policy or included in a general covering clause, the property of a servant is not replaced when loss occurs under the policy held by the head of the family. Another item not generally known is that when a loss is paid by an insurance company the amount is deducted from the sum insured until the renewal premium is paid or a new insurance equal to the amount of the loss paid has been effected. That is to say, if A, who is insured for £500, has a fire in May, and recovers £400, and the renewal premium on his policy is due the following December, during the period from May to December he is covered for £100 only, unless he re-insures. Mr. Jarvis's and Mr. Woods's book should be of help to the majority of householders; and if, at some future time, they could add to it, or issue in a separate form, some hints on what to do, and what not to do, when some of the usual domestic inflictions occur—when, for instance, the electric light suddenly goes out and no mechanic is at hand to put in a simple fuse-wire; or when there is a smell of gas in the kitchen for the want of half-a-pint of water poured into the telescopic pendant; or when the house is being flooded with water through a burst pipe for want of screwing down the cock on the main supply pipe, or, if that be missing, flattening the pipe itself with a hammer; or when the householder is told by the domestic that the "telephone man" or "inspector of water fittings," whom she admitted half-an-hour previously and permitted to roam over the house without so much as having a shadow of doubt as to the *bona fides* of his errand, has walked off with one or more valuable articles,—well, if they can add a few chapters on similar points to these to enlighten ourselves and to teach our domestics wisdom, they will earn the gratitude of a large number of their fellow men.

JOURNALS.

The Middlesex Hospital Journal.—The *Middlesex Hospital Journal*, which is edited by Dr. Campbell Thomson and Mr. C. Reissmann, has devoted its July number almost entirely to historical matters connected with the hospital and school. The "Story of the Middlesex Hospital" is very ably told by Dr. Sidney Coupland in a manner which cannot fail to interest everyone who reads it. "The story" is to be continued in the future numbers of the *Journal*, and when finished it will form a valuable record of the history of the hospital from the time of its foundation to the present day. Dr. Coupland deserves the best thanks of Middlesex Hospital men for the labour and time which he must have spent in giving them such an interesting and authentic account of their hospital. Mr. Stephen Paget contributes a good article on Sir Charles Bell, which deals more especially with his early life in London—"the time of waiting before his prosperity became well-nigh burdensome to him." The account of the new cancer wing and the illustrations of the new school buildings show that the future, like the past, is to be one of continual progress, for the new school buildings, which are now almost finished, will put the hospital in possession of an admirably organised medical school. The illustrations are numerous and include an excellent picture of Sir Charles Bell and the hospital staff in 1865, and various views of the hospital at different stages of its career. The *Journal* is well got up and we wish it success.

In the *Phonographic Record* for August, Dr. Fletcher Beach continues his descriptions of mentally deficient children, and Dr. James Collier narrates a remarkable case of vesical fistula in a paraplegic patient under the care of Sir W. R. Gowers at the National Hospital for the Paralysed and Epileptic. After retention of urine for five months, during which the bladder was not relieved by the catheter, a lump appeared in the patient's right groin, burst in a few days, and through the opening left the patient voids all his urine nothing coming *per urethram* but a little pus.



PRESENTATIONS TO MEDICAL MEN.—At a public meeting at the Drill Hall, Llandovery, on July 30th, his worship the Mayor of the Borough presiding, Mr. F. W. Lewis, M.R.C.S. Eng., L.S.A., medical officer of health of the borough and of the Llandovery Union, was the recipient of several gifts in recognition of his twenty-five years' services to the poor and rich alike. Over 800 persons subscribed and but for the collecting books being closed too soon more subscriptions would have been forthcoming. Nevertheless, about £250 were collected. The testimonial comprised chased and pierced fruit dishes, two pairs of silver Corinthian candlesticks, a silver fluted Georgian tea-kettle and stand, a silver fluted Georgian hot-water jug, a grand piano, and a secretaire in dark oak with revolving chair to match. On the kettle was engraved the following inscription: "Presented with four silver fruit dishes, two pairs of candlesticks, hot-water jug, desk, and chair to Dr. F. W. Lewis, Llandovery, by the inhabitants of the town and neighbourhood, as well as by the employés of the London and North-Western and Great Western Railway companies, as a mark of their appreciation of his long services amongst the poor and needy of the district and his unfailing courtesy to those amongst whom he lives. July 30th, 1898."—To mark the completion of some twenty-five years' practice in the Kintore district the friends of Mr. John Cameron, L.R.C.S. Edin., availed themselves of the opportunity to express in some tangible form an appreciative estimation of his services, both professionally and socially. The Oddfellows Society, with which Mr. Cameron has been associated as medical officer, took the initiative and opened a subscription list. A considerable sum was collected and on July 27th, at the public hall, Mr. Cameron was presented with a silver tea and coffee service. — At the meeting of the Committee of Visitors of the Joint Counties Asylum of Carmarthen, held on July 28th, the chairman (Mr. W. O. Brigstocke), on behalf of the committee, presented to Mr. Edwin Goodall, M.D., B.S., M.R.C.P. Lond., the medical superintendent, a silver teapot, cream jug, and sugar basin as a mark of their respect and esteem on the occasion of his recent marriage.

New Inventions.

A NEW PATTERN OF UTERINE REPLACER.

THE instrument figured below was the outcome of difficulties occasioned by a case of uterine displacement caused some months previously by a severe fall which occurred abroad in a place some three or four weeks' journey removed from the help of any instrument maker. The patient, a married nullipara, had cessation of the menses without any symptoms pointing to pregnancy. Digital examination revealed the uterus completely anteverted. By curving an ordinary uterine sound to a right angle it was introduced to the fundus after much difficulty, but the angle to which the sound was bent prevented its being rotated, nor could any form of stem be introduced to help to replace the uterus, and chloroform was steadily refused. The instrument figured was devised and made in two weeks entirely by myself and has one or two important points. It is made entirely of metal—German silver; its parts are fixed together by screws, so that it can be readily

The upper figure is a plan showing the screw rod which works the probe through different angles. The middle figure shows the instrument itself. The lower figure shows the handle for working the screw rod.

taken to pieces, if necessary, for thorough disinfection; and also during its use, while the right forefinger retains its position at the os externum, it can readily be manipulated backwards or forwards by the left hand turning the screw nut, the length of the end of the screw projecting beyond the nut serving as an index to the position of the probe end of the sound. It is sufficient to say that in a week or two after its employment the uterus in this case was restored to its natural position, menstruation was re-established, and a month after all treatment had been suspended the uterus was still in its normal position. There is nothing new under the sun, but I do not know of any instrument which possesses the useful points of the above, and having served me well I trust it may be of use to others. Messrs. Matthews Bros., of 10, New Oxford-street, have undertaken its manufacture.

THE *RÔLE* OF THE MOSQUITO IN THE EVOLUTION OF THE MALARIAL PARASITE.

THE RECENT RESEARCHES OF SURGEON-MAJOR RONALD ROSS, I.M.S.

AT the meeting of the British Medical Association in Edinburgh Dr. Patrick Manson, the President of the Section of Tropical Diseases, gave by special request and with the permission of the Secretary of State for India and of Surgeon-Major Ronald Ross, I.M.S., a lecture and exposition of the work done lately by the latter in the investigation of this subject. Surgeon-Major Ross has also sent us an advance copy of his recent report on the cultivation of Proteosoma, Labbé, in grey mosquitos. From this report we make the following extracts:—

"*A discovery of pigmented cells in grey mosquitos fed on larks with proteosoma.*—In February, 1898, I was placed by the Government of India on special duty to prosecute these researches and was given the use of Surgeon-Lieutenant-Colonel D. D. Cunningham's laboratory in Calcutta for the purpose. Steps were immediately taken to find again, if possible, the pigmented cells by feeding different species of mosquitos on blood containing different species of gymnosporidia. It was found that Calcutta abounded in the grey or barred-back species of mosquito, which is the filaria-bearing species, and with which I had already experimented. These had uniformly yielded negative results in Secunderabad when fed on blood containing crescents. Nevertheless, owing to difficulties in the way of obtaining other varieties, both of mosquitos and of malaria cases, numbers of this kind were again fed on a patient infected with crescents. Out of forty-one of these searched exhaustively for pigmented cells not one contained them. An unrecorded number, say fifty more, examined unfed, or, after feeding on healthy persons, gave similar negative results. As it was not the malarious season of the year, and as cases of hæmamœbiasis suitable for these experiments were not at all easy to procure, it was thought advisable to commence work on the so-called malaria parasites of birds. Accordingly a crow (*Corvus splendens*) and two tame pigeons infected with halteridium were obtained; and on the night of March 11th and 12th these, with four short-toed larks (*Calandretta dukhunensis*) and six sparrows (*Passer Indica*), whose blood had not yet been carefully examined, were placed in their cages, all within the same mosquito netting, and a number of grey mosquitos of the species I had lately been experimenting with were released within the net. Next morning numbers of these insects were found gorged with blood and were caught in test-tubes in which they were kept alive for two or three days.

"On March 13th I commenced to examine them. Out of fourteen of them pigmented cells were at last found in one. Believing as I did that these cells are derived from the gymnosporidia I judged from this experiment that the grey mosquito which now contained them had fed itself on one of the birds which happened to be infected by a parasite capable of transference to the grey species of mosquito. As all the birds had been placed together in the same net the question now was which of them had the mosquito fed herself upon. This could be easily ascertained. A number of mosquitos of the same species had meanwhile been fed separately on the crow and two pigeons with halteridium; but out of thirty-four of these examined not one contained pigmented cells. Hence I came to the conclusion that the mosquito with pigmented cells had not derived them from the crow and the two pigeons. The larks and sparrows remained. The blood of these had not yet been carefully searched. I now found that three of the larks and one of the sparrows contained proteosoma (Labbé) and therefore thought it possible that the mosquito had been infected from one of these. Accordingly, on the night of March 17th and 18th a number of grey mosquitos were released on the three larks with proteosoma and next morning it was found that nine of these had fed themselves. On the morning of March 20th—that is, from forty-eight to sixty hours after feeding—these nine insects were examined. Pigmented cells were found in no less than five of them. After the long-continued negative experiments with this kind of mosquito

Digitized by Google

(and, indeed, I may say, after three years' doubtful attempts to cultivate these parasites) this result was almost conclusive. It indicated, as was surmised before, that when a certain species of mosquito is fed on blood containing a certain species of gymnosporidia pigmented cells are developed. Hence it would follow, as an easy corollary, that the cells are a stage in the life-history of the gymnosporidium in the mosquito.

"It was now necessary, however, to confirm and amplify this observation and obtain formal proofs of the theorem by repeating these experiments and by studying the pigmented cells themselves. Accordingly from March 18th to the present date (May 21st, 1898) many differential experiments have been completed by feeding grey mosquitos as follows: (*a*) on larks, sparrows, and a crow with proteosoma; (*b*) on crows, pigeons, and other birds with halteridium only; (*c*) on a lark and a sparrow with immature proteosoma only; (*d*) on a healthy sparrow. Only the insects fed on group (*a*) have contained pigmented cells.

"MacCullum had previously shown that in the case of the analogous parasite—the halteridium—the flagellum, of the flagellated phase, after breaking away entered certain spherical, pigmented halteridia, causing them to be transformed into little travelling pigmented vermicules, which, in virtue of their sharp beak and mechanical power, traverse freely red and white corpuscles. Analogy suggests that namely, the body cavity of the host—there appear to be no means by which they can escape from that host during its life to undergo sporulation in external nature, as is the case with coccidium oviforme. It would appear then that sporulation should occur either within the living host, as with eimeria, or within the dead host. The first would point to a completion of the life cycle by a direct infection of men and birds by the coccidium spores in the mosquito; the second to a more circuitous infection, perhaps by a second generation living free in water."

In the paper read by Dr. Patrick Manson at the Edinburgh meeting of the British Medical Association the speaker was able to quote from telegraphic communications with Surgeon-Major Ross which showed that the further researches spoken of have been undertaken. The next stage seems to be that the coccidia now burst and what Surgeon-Major Ross calls germinal vermicules which had formed in its interior are set free in the body, blood and tissues of the mosquito. Then came a step in the investigation of great consequence: it was no other than the discovery of these vermicules in the venemo-salivary glands of the mosquito. Surgeon-Major Ross during dissection of the mosquito found a couple of head glands with a duct leading towards the proboscis of the animal and traced the parasite vermicules into these glands. The climax of the discovery was now within his grasp and

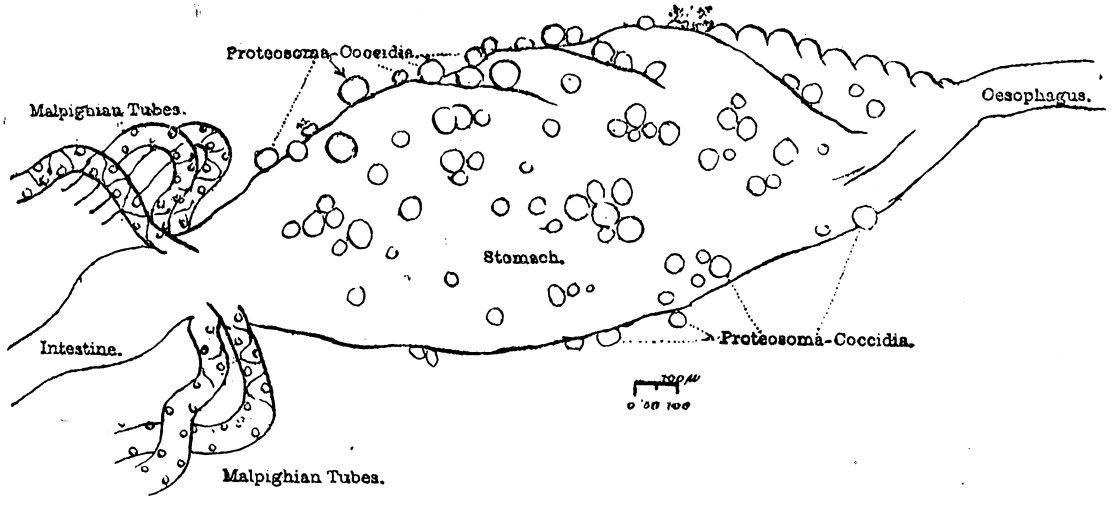

Figure reproduced from Surgeon-Major Ross's report and showing appearance of coccidia on the sixth and seventh day.

a similar thing occurs in proteosoma and that the travelling pigmented proteosoma vermicule enters the tissue of the mosquito's stomach and becomes Ross's pigmented bodies, in the same way as Manson has shown took place in the case of the filaria sanguinis hominis. Arrived in the stomach wall of the mosquito, the proteosoma increases rapidly in size until it projects beyond the stomach walls into the cœlom or body cavity of the mosquito as a rounded body, which he styles the proteosoma-coccidia. During its progress and growth various changes take place in size and in the appearance of the contents of the coccidia. Pigment diminishes and then disappears and as the parasite protrudes into the cœlom it is seen that the contents have a more or less granular appearance.

"I have said that after this point I have witnessed no further growth of the coccidia, even in mosquitos kept alive to the twelfth day. Hence we may perhaps expect that they have become ripe for sporulation. No such thing has, however, been observed; and we may therefore conjecture, unless I happened to have overlooked it, that it may occur either (*a*) in the living insect after twelve days, or (*b*) some time after the insect's death. Further research is therefore required on this which now becomes the most important and interesting period of the life-history of the gymnosporidia, because on it depend our chances of future progress. To plunge into hypothesis for a moment we may remark that since the mature coccidia find themselves in a closed cavity—he elucidated it thus: He allowed mosquitos to feed on birds infected with proteosoma; after a few days he fed the mosquitos on birds whose blood was void of any parasite infection. He found in due course that the parasite-bearing mosquito had infected the healthy birds and that their blood was charged with proteosoma.

Thus the analogy between bird and human infection has only to be proved to establish that the mosquito is a carrier of malaria and an infector of man. Much has yet to be done, however, before the full significance of the mosquito in malaria is worked out. Malaria, we know, multiplies without the intermediary of any vertebrate. Does it do so solely in mosquitos? If so, we have yet to learn how it passes from mosquito to mosquito. Does it multiply in other media? If so, what are they? There is here given merely the outline of Surgeon-Major Ross's work. Doubtless he or others will soon grapple with the other problems it suggests and show how to solve them. It is impossible in a short space to give in detail the multitudinous experiments and observations which he has carried out. Suffice it to say that they have been done in a masterly way. The practical applications of the discovery are immeasurable and the establishment of the fact that as the bite of the snake or the rabid dog inoculates the blood of the victims of these creatures so the mosquito conveys malaria, would open up a new and hopeful phase as regards the prevention of disease in the tropics.

THE LANCET.

LONDON: SATURDAY, AUGUST 20, 1898.

A QUESTION of considerable importance to students, and one concerning the working of our medical schools, was asked by Mr. ARTHUR O'CONNOR in the House of Commons last week. The question was whether the Home Secretary was aware that a poor woman expecting her confinement frequently applied to one of the general hospitals in London for a medical man to attend her and that in such a case a student was often sent who had had little or no experience, or might even never have attended a case before, and that no intimation was given that the person sent was not a fully qualified medical practitioner, and whether the General Medical Council had not prohibited the employment by private practitioners of assistants who, although they had taken out a full course of midwifery training, had not taken out a degree in medicine, surgery, and midwifery. Mr. JESSE COLLINGS replied for the Home Secretary that he had no information, but that full inquiries would be made upon the subject. Before discussing the question at all we would call attention to the last paragraph of the General Medical Council's resolutions respecting the employment of unqualified assistants. It reads as follows: "The foregoing notices do not apply so as to restrict the proper training and instruction of *bonâ-fide* medical students as pupils, or the legitimate employment of dressers, midwives, dispensers, and surgery attendants under the immediate personal supervision of registered medical practitioners." It must be admitted that there is no specific mention made of the students employed in the maternity departments of all our large general hospitals, but that they are intended to be included under the generic term "dressers" there can be no doubt.

To anyone imperfectly acquainted with the true facts of the case it might appear as if the resolutions of the General Medical Council were being set at defiance under the circumstances mentioned by Mr. O'CONNOR, but a little consideration of the matter will show that this is far from being the case. It is, of course, quite true that when a poor woman applies at a general hospital for attendance at her confinement a student is sent to the case, but the patient and her friends, although they commonly dub him "doctor," know full well that he does not represent the whole of the medical assistance they can, if necessary, obtain. They know that if the labour is in any degree abnormal they will have the services of a gentleman whom they often call "the head doctor," a registered medical practitioner, the obstetric assistant, under whose direct personal supervision the students attend such cases and to whom they are directly responsible. Further, they know that in cases of extreme urgency they can have the benefit of the skill and experience of one of the obstetric physicians attached to the hospital at which they have applied for assistance. It is obvious that a student who is attending his first case has had no previous experience, but in a properly conducted maternity department due provision is taken to guard against a student being allowed to go to his first case alone, and until he has a satisfactory theoretical knowledge of his subject. One of the rules which should be always insisted upon—and in many places is so—in the conduct of an extern maternity department is that the student shall be accompanied to his first cases by one or other of the obstetric assistants. There is to our mind no comparison between the position of the patient attended by a medical student who is not even allowed to assume as much responsibility as an ordinary midwife, and who is working under the immediate supervision of a fully qualified medical practitioner, and that of the patient who is attended by an unqualified assistant. No doubt in many cases the unqualified assistant is a man of much skill and experience, and well fitted to deal with any of the complications of midwifery. The position he holds, however, in the mind of the patient is that of a private practitioner and not in the least that of a hospital medical officer, and although she is quite ignorant of the subtleties of qualifications, yet she knows well enough that there is a difference between the private practitioner with a brass plate or a surgery and the student who comes to attend her when she sends to the hospital. Then, again, the degree of responsibility assumed in the two cases is entirely different. The student, as we have pointed out, is not allowed to assume even as much responsibility as the ordinary midwife, while the unqualified assistant, in charge as he often was of a branch practice of his principal, assumed the entire responsibility of, and often conducted single-handed, cases of difficult and complicated labour. It would not be possible to carry on a large extern maternity department at any of our schools if the General Medical Council insisted upon the students being accompanied in every case by a qualified medical practitioner. It would entail the appointment of a large number of obstetric assistants, and although it would undoubtedly increase the value of the students' training in midwifery yet it would be impracticable under present conditions.

The training of our London students in midwifery is certainly deficient, but we are afraid that it will continue to be deficient. Even if the necessary lying-in hospitals at which students could be trained under the eye of experienced resident officers were built we doubt very much if the patients could be induced to enter them. Our own experience is that the women in the majority of cases find it more convenient and cheaper to be confined at their own homes; and it is often difficult enough to get them to go into a hospital even when they have been told that their confinement may be a difficult or a dangerous one. The practical inexperience of the student attending his first case cannot obviously be overcome. We think, however, that the rules laid down at most of our medical schools are amply sufficient to provide against the danger of any student attending a case without at any rate a good theoretical knowledge of his subject. It is, we gather, the general custom not to allow a student to take an appointment in the maternity department until he has

Digitized by Google

attended the courses of lectures in midwifery, both theoretical and practical, or, as owing to the exigencies of working the department it is sometimes necessary to appoint a student before he has had time to finish his courses of lectures, until he has satisfied some responsible person—usually the obstetric physician in charge—that he has a sufficient amount of knowledge of the subject to admit of his being placed upon the roster for duty. Regulations of this kind, together with the rule that one of the obstetric assistants must always accompany students to their first cases, would seem to be amply sufficient to ensure that the student shall be able to recognise any abnormality in the cases which he attends, which is strictly all that he is required to do. We have no doubt that the General Medical Council will be able to assure the Home Secretary that the positions of the student and the unqualified assistant are not one and the same, and that the safeguards at present in vogue in our maternity departments are such as to obviate any risk of the contravention of their resolutions with regard to the employment of unqualified persons as assistants or otherwise.

WHILE it is highly proper to note the falling off in the amount of the Metropolitan Hospital Sunday Fund collection for 1898 it would be wrong to attach too much importance to it or to indulge in any hasty theory by way of explanation. The whole circumstances of the last two years have been such as to produce slight irregularities in the yield of the ordinary sources of hospital income, amongst which the Hospital Sunday Fund must always rank high. It is the greatest tribute to HER MAJESTY'S reign that it has stimulated humane and benevolent work in a degree unprecedented in any previous period. The multiplication of charities is enormous, and the number and variety of the demands for voluntary contributions towards all conceivable objects—some of them questionable, many of them excellent—have increased proportionately. No one can have failed to notice the increase of late both in number and insistence of requests for money to be allotted to the particular purpose of supporting hospitals. Changes in the economic conditions of the country have so profoundly affected the incomes of some of our principal metropolitan hospitals that special appeals on their behalf have had to be made and the response to such appeals by the public has been very generous. When memorials of HER MAJESTY'S reign were being devised nothing fitter could be suggested than a fund for the mitigation or removal of hospital indebtedness. The appeals for the individual hospitals and the organisation of the PRINCE OF WALES'S Fund have the powerful support of His Royal Highness and other members of the Royal Family, and the real matter of surprise, perhaps, is that these special circumstances have not affected the Hospital Sunday Fund more, rather than that they have affected it a little.

Sir HENRY BURDETT'S theory that the falling off in the Fund is largely due to the creation of limited companies is not to be dismissed hastily, but it was very well answered by Sir SYDNEY WATERLOW. Besides, it is scarcely consistent with the former gentleman's belief that the hospitals individually have been faring better. If the moral effect of limited companies is good for the individual hospitals it can scarcely be bad for the Hospital Sunday Fund. It would be lamentable, indeed, if the limited company system, which seems destined to play so great a part in the evolution of commerce, has the moral effect on individuals which is thus attributed to it. According to Sir H. BURDETT there are 10,000 of these companies now in England, and the operation of them is to weaken the sense of individual obligation to charities. It is difficult to reach individuals and to estimate their power to help charities when they are all mixed up together in commercial adventures. In that sense it is difficult to apportion their responsibility to the great charities of the land and those who like to shirk such responsibilities may take the advantage of their being, so to speak, in a crowd. But we are unwilling to believe that there are many individuals who would do so. The Hospital Sunday Fund owes its largest collection to a prosperous year on the Stock Exchange, and whatever may be the sins of the members of that body they have never been insensible to the cry of the helpless and the sick. We come to the conclusion that we must look in other directions for the causes of the slight decrease in the Hospital Sunday collection for 1898. Sir H. BURDETT is as confident in exempting the PRINCE OF WALES'S Fund from any blame for the diminished amount of the Hospital Sunday Fund as in his conviction that the growth of limited liability companies affords the explanation. He may be right. And we feel sure that neither the PRINCE OF WALES nor any one of his colleagues desires any injury to the Hospital Sunday collection. In this belief we do not permit ourselves to doubt that care will be taken next year to avoid the repetition of an unfortunate appearance of competition by the issue of a report and appeal from the PRINCE OF WALES on the very eve of Hospital Sunday. To our own knowledge this report, dated June 6th, was received by some persons on the day before Hospital Sunday.

The Council of the Hospital Sunday Fund will fail in its duty if it relaxes its vigilance or rests too much on its oars. Though it has refused any formal inquiry into the decrease it ought to take pains to ascertain exactly where the failure is and to prevent the recurrence of it next year. In one thing the Council of the PRINCE OF WALES'S Fund promises to set the older Council a good example: it intends to satisfy itself as to the merits and needs of the hospitals and to be guided by the results of its inquiry into these. The Council of the Hospital Sunday Fund has been apt to regard itself as a mere dispenser of gifts for hospitals without any corresponding responsibility for the efficiency of the hospital system and for the prevention of those abuses of it which hinder charity and demoralise unfit recipients. There have been indications of late of a larger view of its duties and obligations. If these are fulfilled the Fund will have a future of lasting prosperity. It has the religion of the metropolis for its foundation and that will not fail. Other influences must vary and must be more or less temporary, but this abides. The contributions of the wealthy should still be personal and distinctive. Our own belief is that with deeper religious views among those who are stewards of wealth large personal gifts will be "cast into the treasury," such as that of GUY himself, which will raise

Digitized by Google

the committees of hospitals out of all petty cares—for instance those somewhat pathetically expressed by the Hon. SYDNEY HOLLAND, chairman of the London Hospital—about the balancing of income and expenditure. Half-a-dozen rich men have it in their power to do this great service and to redeem wealth from discredit and all the risks which attach to its possessors, and they can have no better medium through which to do it than the Council of the Hospital Sunday Fund.

THE answer of the Chancellor of the Exchequer to Dr. FARQUHARSON on July 19th with reference to the matter of a grant of public money to the General Medical Council contained, we are glad to see, no hint that Parliament would be unwilling to give the Council increased powers and we hope to see the question revived in a more definite form. The purification of the medical profession, to be thorough, would of necessity involve the prohibition of unqualified practice. For what happens at present in the medical and legal professions respectively? A solicitor is struck off the rolls and by that process he is debarred from following the profession of a solicitor. A medical man is struck off the Register and he abides in his own house, his plate is still on the door and he continues his practice as if nothing had happened because it is not against the law for an unqualified or unregistered person to practise. There is nothing more unfair than the position in which the medical profession stands to-day. A man may have gone through years of study, have passed several searching examinations, have held appointments involving very hard work and great responsibility while receiving little or no emolument for the same, and despite all this any ignorant swindler who has never seen the inside of a hospital, who knows no anatomy or physiology, and who is ignorant of the action of any drug, has similar rights with him to see patients or to prescribe and give away (not sell) drugs. The sole advantages which the qualified and registered man possesses over his unqualified competitor are those of being able to sign a legal death certificate, to sue for fees in a court of justice, to compete for certain appointments, and of exemption from certain civic duties. These are but a poor return for five years of hard study and the expenditure of at the very least £1000, and the only way in which the unqualified practitioner becomes amenable to the law is in case he "wilfully" and "falsely" pretends to be a registered person. The net of the Solicitors Act has a much smaller mesh. By it there need be no question of either "wilfully" or "falsely" pretending—the mere fact of such pretence having occurred is quite enough to secure a conviction.

That the position of the medical profession is as it is to-day is owing mainly to two factors. The one is the carelessness and want of cohesion among members of the medical profession themselves and this factor is by far the more important. Parliament never does anything for any body or persons unless they possess the power of annoying Ministries by their actions within the walls of the House, or, as was the case with the Dissenting community at the time of the Church rates agitation, can show a solid consensus of opinion outside the House. Now the medical profession at the present moment is not an organised nuisance either within or without the House of Commons and accordingly if any legislation affects it at all it does so adversely. The other factor, less significant than the apathy of the medical profession, but not without its evil influence, is the fatuity of the average British citizen in matters concerning his health. It is nothing new. To go no further back than the beginning of the century the notorious quack ST. JOHN LONG was able to bring plenty of witnesses, drawn from the upper classes of society and from those who had received a good education, to bear witness to the efficacy of his treatment. Numbers of persons of influence in their respective spheres are still of the opinion of Lady SOUTHDOWN, who it will be remembered remarked of a regular apothecary: "A most dangerous and ignorant practitioner ..... I have providentially been the means of removing him from several houses, though in one or two instances I did not arrive in time. I could not save poor dear General Glanders, who was dying under the hands of that ignorant man—dying. He rallied a little under the Podgers' pills which I administered to him; but, alas, it was too late. His death was delightful, however, and his change was only for the better." *Mutato nomine*, the same thing exists nowadays, only instead of Podgers we have the reverend specialist for this or that, the bone-setter, the herb-doctor, and the exponent of safe medicine or "natural" therapeutics.

The prohibition of unqualified practice is outside the sphere of practical politics. Parliament as a body would never move in the matter, first on account of prevalent ideas concerning personal freedom, and secondly because many of its members are enamoured of unorthodox medical practices themselves. But we can at any rate demand that no one who has not been through a recognised medical curriculum shall be able with impunity to delude the public into thinking that he is a medical man by assuming the title of "doctor," for the public as a whole considers that the term "doctor" applies solely to the profession of medicine. Again, in the case of a felon the body or bodies which have conferred upon him degrees or diplomas should have the power to remove his name from their rolls upon his conviction and to place him on a footing with persons of the FERNANDI type—to recall to the recollection of our readers a particular quack. The knowledge of the felon, of course, will be the same after his conviction as before, but he should not be allowed to practise, under a title which implies respectability, a profession which entails a keen sense of honour and responsibility. The monopoly at present enjoyed by members of the legal profession will never be ours, for it is of the very essence of codes of law that there should be no room for individual opinion. But liberty in the matter of irregular practice has degenerated into license, and the medical profession as a whole has a right to ask that some restraining influence should be brought to bear upon the ignorant and the criminal so as to prevent their reaping where they have not sowed.

IF there be one disease more than another concerning which the pathologist might well be entitled to say that he had complete knowledge it would be the condition

Digitized by Google

known as portal cirrhosis of the liver. Constituting a well-marked variety of interstitial hepatitis, its characteristics are so well defined and its concomitant lesions so well marked that from the etiological standpoint it used to seem enough to refer it to a single antecedent—namely, chronic alcoholism. As knowledge has grown pathologists have been less inclined to accept so limited a conception of the manner of its origin and cases have not been wanting where it would seem that other toxic agencies, some of which have probably been due to specific infections, have operated to bring about those lesions which ultimately result in the familiar hob-nailed contraction of the organ with its accompanying obstruction of the portal circulation. Yet so far as we know the cases in which alcohol can have played no part are comparatively rare. It is otherwise with some other forms of progressive interstitial hepatitis, such as that which is associated with syphilitic infection or that where the general intercellular framework is involved, producing the variety known as "monolobular," "biliary" or "hypertrophic" cirrhosis. The last-named condition—which, it may be remarked, is not universally deemed to be specifically distinct from the multilobular variety—has been far more frequently referred to the action of infective agencies, so that less surprise may be occasioned by the discoveries made by Professor ADAMI, as described by him in the paper which we published in THE LANCET of August 13th, in respect to this form of cirrhosis than must necessarily be the case in regard to the more familiar type. For we venture to think that many clinical observers as well as pathologists will receive with something like amazement the announcement that micro-organisms have any share at all in the production of portal cirrhosis.

Let us very briefly summarise the observations which have led Professor ADAMI to a conclusion which, if correct, cannot but have important bearings upon the conception of the process of progressive inflammatory changes in all organs and not merely in the liver. The determining influence in his inquiry into hepatic cirrhosis in man was his discovery, after much patient labour and care in preparation, of a definite microbe in an infective disease of cattle, known as the Pictou disease, which for several years attacked the herds in Nova Scotia. The fact that this affection—obviously transmissible as it was—was characterised by a form of progressive hepatic cirrhosis was first ascertained by Professor W. OSLER and Dr. WYATT JOHNSTON and amply confirmed by Professor ADAMI, who was instructed to continue the investigations initiated by them. Professor ADAMI, however, also succeeded (in each of the animals which he examined) in isolating a definite micro-organism from the abdominal glands and liver-juice as well as occasionally from other organs and fluids. The microbe was of small size and exhibited a polymorphous character which added to the difficulties of its recognition. He succeeded, however, in cultivating it in various media and found that it was pathogenic for rabbits, guinea-pigs, and mice, and that it was essentially a short encapsuled bacillus somewhat resembling the organism of hæmorrhagic septicæmia in the lower animals. He does not appear to have given this organism a name, but he thinks that its characters are sufficiently definite and its appearance in the Pictou cattle disease sufficiently constant to warrant its being regarded as the pathogenic agent in that infective disorder.

Now we doubt not that many bacteriologists would have been content to have stopped here, for it would hardly enter into their minds that this special infective disease of cattle could possibly have any relations with so common and so chronic an affection as cirrhosis of the liver in man. Not so Professor ADAMI. He felt that in spite of superficial differences there were certain marked resemblances, both clinical and pathological, between the bovine and human diseases. He did not arrive at this opinion suddenly and when he did set out upon his search for microbes in the liver and other tissues of the subjects of cirrhosis he met with many difficulties, especially in the matter of staining. At length he was enabled to detect, with an uniformity which excludes the idea of accident or of external contamination, a minute microbe which evidently requires great patience and skill in its discrimination. Moreover, like the Pictou disease organism, it presented itself under more than one form, although we gather from his remarks that Professor ADAMI is inclined to attribute this polymorphism in part to differences in intensity of staining. He found, however, some purely coccal forms and some bacillary. The microbe occurred within liver cells and in the midst of the actively growing connective tissue, the small-celled infiltration which is so characteristic of cirrhosis, and he subsequently found it elsewhere in the body. He did not at first venture to identify the organisms thus detected in the human disease with those present in the bovine, but the case which he examined just as his paper had been completed seems to have possessed characters and yielded reactions so closely resembling those of the Pictou disease as to raise more than a suspicion of their identity.

In his paper, which must in truth be regarded only as a preliminary note, for the subject requires much working out, Professor ADAMI wisely refrains from speculating upon the bearings which his discovery must necessarily have upon our conceptions of the nature of the hepatic cirrhoses. We say "the cirrhoses," for he has found these organisms in more than one variety of these interstitial inflammations of the liver. Nor shall we venture to go further than he has done. We have such respect for his acumen and ability as a pathologist and a bacteriologist that we do not think it possible that he could have been misled by *ignes fatui* or have erred in describing as micro-organisms any inert particles of dead matter. Indeed, he has anticipated so obvious a criticism by his cultivations. We accept, then, fully the fact of his discovery, but we reserve the expression of any opinion as to its bearings on pathology, feeling that these are of far wider application than that of the etiology of common cirrhosis. For if these microbes be of pathogenic importance an extension will be given to the *rôle* of the microbe in disease which is well-nigh illimitable. It seems as if the bacteriologist would in time recast all our pathology. His sphere of "infectivity" is fast expanding to embrace conditions which we call "chronic" as well as those which we term "acute." The "trail" of the microbe "is over them all" and none can foretell what the future may reveal.

"Ne quid nimis."

"DRUNK OR DYING?"

ANOTHER of those unfortunate errors in judgment which bring discredit upon hospitals and are indubitably most regrettable was investigated in the Rotherhithe Coroner's Court before the deputy coroner on August 15th. The inquiry was into the death of a carman named James Fisher, aged fifty-six years. At 10 P.M. on the night of August 10th he was thrown out of a van in the Union-road, Rotherhithe, and found lying unconscious on the pavement. A constable summoned a neighbouring practitioner, who gave evidence to the effect that Fisher was suffering from two scalp wounds and was bleeding from the nose and from the ear. Fisher was conveyed to Guy's Hospital on an ambulance. The house surgeon in his evidence said that he saw Fisher a few minutes after his admission; neither his nose nor his ear was then bleeding. He detained him for about one and a half hours—i.e., until 12.15 A.M. He (Fisher) was very drowsy and witness acknowledged that he wrongly attributed his condition to alcohol. As no fresh symptoms developed Fisher was sent to the police-station and charged with being drunk. Here he was visited many times up to 8 A.M., when he was found walking up and down. He said he felt "very queer" and fell down. The divisional surgeon was called and ordered him to be removed to the infirmary, where he died about 11 A.M. on August 11th. At the post-mortem examination a fracture of the base of the skull and two fractured ribs were found. Now we have no wish to conceal the fact that the house surgeon, as, indeed, he confessed, committed a most serious error of judgment, but what we do wish to point out is that the public and the glib newspaper paragraphist have no conception of the difficulties which encompass a house surgeon upon occasions such as the one upon which we now comment. To begin with, in many cases it is all but impossible to distinguish between the condition brought about by brain injury and that due to alcohol. In a great many cases a patient brought in with a scalp wound exhibiting signs of mental disturbance is partly drunk and partly drowsy from cerebral compression. On the other hand, he may be simply drunk and have a scalp wound in addition, which latter has nothing to do with his mental condition; or he may have a scalp wound and cerebral mischief without having taken any alcohol; or, again, he may have cerebral mischief, a scalp wound, and smell strongly of alcohol owing to some injudicious but kindly intentioned person having administered alcohol to him just before his admission. Out of all these varying conditions the unfortunate house surgeon has to make a fairly accurate diagnosis, generally late at night, after a hard day's work, and house surgeons and house physicians, too, are overworked to an extent which would not be tolerated for a moment in the case of a milliner or a factory hand. Cases of this description are brought to a big hospital to the number of about a dozen nightly. It is obviously impossible to take them all in and it speaks volumes for the care and good judgment of our young medical men that such lamentable accidents as the present do not occur oftener than they do. The only means of avoiding such in future is to lay down a rule that every patient with a scalp wound or any patient without a wound who shows signs of mental inhibition should be detained for 24 hours. This will involve an increase of staff and of accommodation, and if the public, as represented by the lay press, which is not unnaturally so ready to find fault, will provide the means for such no one would be more happy than the house surgeon or house physician. Only those who have held such posts know what the responsibility means, and though we offer our sincere condolences to the relatives of the deceased we are none the less sorry for the house surgeon in question.

PUBLIC ABATTOIRS FOR DUBLIN.

IN view of the Congress of the Royal Institute of Public Health, which commenced in Dublin on August 18th, Dr. C. F. Moore sent to the *Dublin Press* a letter putting forward some suggestions for the consideration of the said Congress. Briefly, they are as follows: that powers should be acquired to erect an abattoir and knacker's yard on the reclaimed ground near the Alexandra Basin; that similar powers should be acquired for the erection of like buildings on the Pigeonhouse-road; that compulsory powers should be sought for the use of these establishments, for the abolition of the sixty knackers' yards and slaughter-houses at present in the city of Dublin, and of the present most ill-placed abattoir outside the borough boundary. Dr. Moore goes on to say that these measures will be imperatively called for when the new scheme of main drainage is carried out. We quite agree with Dr. Moore and, in fact, would go further and say that private slaughter-houses should be done away with everywhere under all conditions. Their existence is a fruitful cause of cruelty, "nuisance," and disease, for meat-inspection cannot be properly carried on except in a public abattoir. As for knackers' yards, they must exist, but they should certainly never be allowed within the vicinity of inhabited houses, however carefully the business is carried on, and we do not imply that this is not the case in most instances. A knacker, it must be remembered, is not only one who kills healthy but disabled horses, but one who gets rid of hopelessly diseased horses and other animals, in addition to which he generally carries on the trade of boiling flesh and offal for cat's-meat. Such an occupation is most certainly one to be carried on at a distance from any collection of inhabited houses. We are far from saying that London is faultless in these matters, but it is gradually getting better, and it behoves Dublin, a city which being very much smaller can bring about reforms more easily, to take Dr. Moore's advice seriously to heart and to begin to set her house in order.

THE FUNCTIONS OF THE SUPRARENAL CAPSULES.

AN interesting memoir by M. P. Langlois appears in the recently published *Travaux du Laboratoire* of M. Charles Richet. M. Langlois' observations were made upon frogs, rabbits, guinea-pigs, and dogs. In frogs the presence of peculiar bodies was first noted by Swammerdam, who mentioned them under the name of corpora heterogenia, but it was only in 1842 that Gruby pointed out the analogy of these bodies to the suprarenal capsules of other vertebrates. Ecker, Pettit, and others described them at greater length. They form in these animals a mammillated band or tract of yellowish colour situated on the ventral surface of the kidneys, and are either seated on the veins or in the walls of these vessels. M. Langlois' first experiments were upon the effects of destruction of one or both of the capsules in the frog—the destruction being accomplished by means of red hot platinum wire—and he satisfied himself that death invariably follows destruction of both capsules, though not of one alone, and that the fatal issue is not due to the shock of the operation or to any inhibitory action being exerted, but to the suppression or abolition of organs essential to life. The grounds for this opinion are that no marked symptoms are observed during

Digitized by Google

the first twenty-four hours after total destruction, secondly because the fatal result is postponed when the destruction is incomplete, and lastly because the subcutaneous insertion of fragments of the kidney with the capsules prolongs life, though such a proceeding would be without influence on the phenomena of inhibition. Although death is the invariable consequence of the destruction of both adrenals the duration of the survival varies. The average duration of life after the operation is about forty-eight hours, but in winter, and in the hybernating frog, life may be prolonged for twelve or thirteen days. The first symptoms observed after the operation are a kind of apathy and indisposition to move even when irritated; then ensued incoördination of the movements, especially of the hinder limbs, followed by complete paralysis, and succeeded by a similar succession of events in the forelimbs; the respiration became slower, the pupils contracted, the cardiac contractions became feebler, the circulation less active, and the animal died. Further experiments have led to the belief that the death of the animal is not due to any disturbance of the renal functions. The conclusion at which the writers arrive is that after the removal of both adrenals there is a true auto-intoxication, the animals generating poisons which are normally either destroyed or changed in the interior of the gland or by some material formed by the gland and poured into the blood. The poisons are probably the products of muscular activity and exert a special influence on the heart and circulatory system.

THE TREATMENT OF ARTERIO-VENOUS ANEURYSM OF THE ORBIT.

IN the *New York Medical Journal* of June 11th, 1898, Dr. J. H. Woodward has published the following case. A woman, aged thirty-nine years, noticed one day a noise in her head which became continuous and distressing and was soon followed by proptosis of the left eye. After six months the veins of the left eyelid and bulbar conjunctiva were dilated; the supra-orbital and infra-orbital vessels were greatly dilated; and especially in the former an aneurysmal thrill was perceptible. With the stethoscope a bruit could be heard above the eye. Compression of the left carotid artery checked the pulsations and stopped the noises. The retinal veins were tortuous and dilated and there were several small retinal hæmorrhages. In December, 1893, the left carotid artery was ligatured. The pulsations and noises were stopped and the proptosis diminished, but the noises reappeared in two months. In May, 1894, the proptosis was much less than before operation and the vessels were only slightly dilated and there were aneurysmal thrill and bruit. Dr. Woodward intended to ligature the right common carotid artery, but finding that compression of the arteries of the collateral circulation at the root of the nose stopped the symptoms he ligatured these. A complete recovery resulted from this operation, of which this is the first recorded case.

VACCINATION AND THE QUEEN'S SPEECH.

THE absence of any reference to the new Vaccination Act in the Speech from the Throne on the closing of Parliament is by no means without its significance. Her Majesty's example in matters affecting the health of her people has always been in the direction of encouraging everything which science and practice have proved to be of real benefit to them, and in no matter has this example been more marked than in the advocacy of vaccination as the real preventive of small-pox. When Parliament was opened the Vaccination Bill was announced by the Queen to the Houses of Parliament and through them to her people. The Bill has passed in a form which causes deep anxiety to a large portion of the more intelligent classes, and in dissolving Parliament no reference is made to it by Her Majesty. It is well known that the preparation of the Queen's Speech is no mere matter of form which is delegated to her Ministers. Hence the significance of this omission.

THE SPIRITUOUS STRENGTH OF ALCOHOLIC LIQUIDS.

THIS must be indeed an age of deception when the resources of the fabricator are directed towards making spirituous liquids appear in the estimation of the public to be stronger than they actually are. It is a common but erroneous idea that the strength of a spirit may be accurately judged by its pungency. This notion has given the adulterator an excellent opportunity. He has hit on the plan of adding to spirits an alcoholic extract of "paprika" or red Hungarian pepper. Thus a sharp taste is communicated to the liquid and though it contains less alcohol it produces on imbibition a greater sensation of warmth than do stronger spirits. The fraud, however, has been brought to light and confirmed by the result obtained after making up mixed spirits in the manner indicated. The method is not merely a fraud, but is likely to cause very serious injury to the health of the consumer.

AID TO DEEP-SEA FISHERMEN.

THE losses by death at Magenta and Solferino amounted to 25 per 1000 in the conquering army, and this, too, was the precise death-rate among the French fishermen who during the season of 1897 frequented the shores of Newfoundland and Iceland for the purpose of catching codfish. In the latter case the casualties, out of a total strength estimated at 14,000 men and boys, numbered 352, but only 64 deaths were due to disease. Shipwreck and drowning accounted for the remainder. It seems, according to Dr. Bonnafy of the French navy, who has just published an interesting pamphlet on the subject,[1] that each fishing vessel carries a series of light flat-bottomed boats which are constructed to fit each other like saucers so as to occupy as little storage room as possible. The vessels having cast anchor the unfortunate sailors go fishing in these frail "dories," of which every year a considerable number disappear with all on board, chiefly during fogs, never to be heard of more. It is in this way that much of the loss occurs, but there is also another source of fatality. In order to save a few hours the captains of certain liners between Europe and North America do not hesitate to cross the bank where the fishermen are at work, and as they do not moderate their enormous speed even in the thickest weather it is easy to imagine how disastrous the consequences may be to the stationary and comparatively minute craft. It is only of late years that attention has been directed to the wretched conditions, hygienic and moral, under which the deep-sea fishing of the North is carried on. As Dr. Bonnafy is careful to state, the credit of initiating reform is due to the British philanthropists through whose efforts the pernicious "Dutch copers" were to a great extent banished from the neighbourhood of the fishing fleets. Our Mission to Deep Sea Fishermen is accorded generous and richly earned praise; but, as the writer explains, there is still ample room for the Société des Œuvres de Mer, whose cause he so warmly advocates. As long ago as 1819 the outfitters of all fishing vessels had to provide medicine chests, and when the strength of the crew exceeded 40 a qualified medical man had to be carried. By degrees, however, the shipowners succeeded in nullifying these beneficent ordinances, until finally in 1864 the strength necessary to entitle a crew to a surgeon was raised to 100, the post being

[1] Secours aux Marins des Grandes Pêches. Toulouse: Imprimerie Lagarde et Sebille, 1898, pp. 22.

Digitized by Google

thus practically abolished. In this unsatisfactory state matters remained up to 1892, when once more public attention in France was directed to the hard fate of the men engaged in the fishing industry. Several minor reforms were at once instituted, and in 1895, under the auspices of the above-named society, the despatch of hospital ships after the English model was decided on. Since then three sailing vessels have been equipped, each making up 30 beds, but the society has had to contend with a series of misfortunes which would have discouraged less strenuous workers. The first hospital ship, the *Saint-Pierre*, was totally wrecked in Placentia Bay. Her sister ship, the *Saint-Paul*, was driven on the rocks at Reykiavik; while the *Saint-Pierre No. 2* had a serious collision with a fishing smack soon after her arrival at the scene of operations. Happily no lives were lost in these deplorable accidents, and in spite of them the society, as Dr. Bonnafy puts it, is running fairly before the wind. In addition to the two renovated hospital ships "family houses" have been established on shore, in competition with the *cabarets* or grog-shops, and are a great success.

THE EARNINGS OF MEDICAL MEN IN FRANCE.

M. HENRI BÉRENGER discourses in the *Revue des Revues* more or less pleasantly, but apparently with authority, on the Intellectual Proletariat in France. Here are some of his observations referable to the medical profession. There are in the whole of France, inclusive of Corsica but excluding Algeria, between 12,000 and 13,000 practising medical men, of whom 2500 live in Paris, the remainder being distributed throughout the provinces. As regards the metropolitan practitioners the following is the approximate scale of earnings: 5 or 6 earn between £8000 and £12,000 per annum, from 10 to 15 earn about £6000, 100 earn £2000, 300 earn between £600 and £1200, 800 earn between £320 and £600, 1200 earn less than £320. Of the 10,000 provincial practitioners not more than half make a decent livelihood. Every year the various universities turn out about 1200 qualified doctors of medicine. The average duration of a practice may be set down as between twenty and twenty-five years; it follows, therefore, that the production is twice as great as the demand. M. Bérenger's statistics may be correct, but apparently he neglects to make allowances for the young medical men who are absorbed each year in the army, navy, and colonial services. 10,000 practitioners for the whole of provincial France seems, moreover, to be anything but a liberal estimate, seeing that the number on the British Medical Register is at least three times greater.

TOXIC EFFECTS FROM THE USE OF CARBOLIC ACID.

TOXIC symptoms have occasionally resulted from the use of carbolic acid as an antiseptic. At a recent meeting of the Société Médicale des Hôpitaux Dr. M. J. Comby related the following case. A child, aged five years, was treated for otorrhœa with carbolic acid. Injections of 1½ per cent. were employed six times a day; after the last injection in the evening five drops of glycerine of carbolic acid (5 per cent.) were instilled and in addition the ear was bathed with the first solution. This treatment was scrupulously carried out for ten days, when the otorrhœa ceased. But two days afterwards the child had persistent hæmaturia and headache. Careful physical examination revealed no other signs of disease and the general condition was satisfactory. Symptoms of acute nephritis—pyrexia, œdema, &c.—were absent; there was no evidence of tuberculosis and the microscope showed that the case was not one of hæmoglobinuria. Dr. Comby therefore concluded that the hæmaturia was due to poisoning by the carbolic acid which had been so sedulously used. The hæmaturia ceased in about a fortnight. Carbolic acid should be carefully used in the case of children, as they are especially susceptible to it.

THE TRANSMISSION OF DELETERIOUS MATTER BY POST.

THE following notice has been issued by the Post Office:—

Deleterious liquids or substances, though otherwise prohibited from transmission by post, may be sent for medical examination or analysis by registered letter post under the following conditions:—

Any such liquid or substance must be enclosed in a receptacle hermetically sealed, which receptacle must itself be placed in a strong wooden, leathern, or metal case in such a way that it cannot shift about, and with a sufficient quantity of some absorbent material (such as sawdust or cotton-wool) so packed about the receptacle as absolutely to prevent any possible leakage from the package in the event of damage to the receptacle.

The packet so made up must be marked "Fragile with care," and tendered at a post-office for transmission by registered letter post. It must on no account be dropped into a letter-box or sent by parcel post. These regulations will be rigidly enforced. Any postal packet of the kind found in the parcel post or any postal packet of the kind, whether registered or not, found in the letter post not packed as directed will be at once stopped and disposed of as the Postmaster-General shall direct.

Any person who sends by post a liquid or substance for medical examination or analysis otherwise than as provided by these regulations is liable to prosecution even if he be a patient sending something to his medical adviser for his opinion, or a medical practitioner sending something to a laboratory or elsewhere.

No liquid or substance of the kind may, under any circumstances, be sent by post to or from any place outside the United Kingdom.

We can ourselves testify to the need that there is for such regulations as the above. It is by no means unusual for samples of matters, both fluid and solid, to reach us packed in an exceedingly careless manner and more than occasionally the containing vessel has perished in the transit, not only to our loss, but also to the damage presumably of other parcels in charge of the Post Office. Many medical men have had the same experience, for specimens transmitted by patients for analysis or microscopical examination are, as a rule, ill-packed, but now that official notice is taken of the matter we have no doubt more care will be taken.

NURSING IN WORKHOUSE INFIRMARIES.

IF it be true that we have the poor always with us it is no less true that the question of their proper care and nursing is a perennial problem which so far seems incapable of solution. At the meeting of the Aylesbury Board of Guardians, held on August 10th, the medical officer, Mr. T. G. Parrott, attended to give reasons why trained nurses should be obtained for the workhouse infirmary. He gave it as his opinion that though he had no complaint to make against the present nurse, yet her standard of nursing was not very high and he considered that a trained nurse would be very desirable. He allowed that there were no cases at present under his care which required trained nursing and also that he knew the master had powers in case of emergency to secure better nursing. The chairman said he could quite understand the medical officer advocating trained nursing, it was only natural that he should be in favour of it as it afforded a good opportunity for someone to help him in his work. It was very kind of the Local Government Board to order things, but that body did not have to pay for them. After a great deal more discussion Mr. Locke moved the following proposition: "Considering that the present nurse has been nursing in the house for three and a half years, and as

Digitized by Google

no complaint has been made, in the opinion of the board the nursing in the house at present is all that is required." This was carried by 16 votes to 5. We consider this a most unsatisfactory result. It is perfectly obvious that in any place where the sick are gathered together away from their friends or relations proper trained nursing ought to be provided for them. The treatment of the poor under the Poor-law has been more or less of a scandal ever since the Poor-law came into operation; the grosser evils have been removed to a certain extent but still much remains to be done, and until some practicable scheme of separating the deserving poor from the profligate, the idle, and the loafer is devised scandals will continue to exist. But sickness is the same and as hard to bear in every class and the sick must be carefully tended.

THE FUNCTIONS OF THE STOMACH.

IN a short article contained in the fourth volume of the *Travaux du Laboratoire* of M. Richet an account is given by MM. J. Carvallo and V. Pachon of experiments they have made with a view of determining whether some of the functions of the stomach, and in particular its chemical, peptic and antiseptic functions, can be vicariously discharged by other parts of the digestive apparatus without detriment to the organism generally. The view that such supplementary action could take place was held by various observers, as by Czerny and Kaiser, and by Filipi and Monari, for they found that dogs from which the stomach had been almost completely removed, survived. Ludwig, however, showed that at least in Czerny's dog an important part of the cardia remained. Ogata, however, endeavoured to demonstrate the correctness of Czerny's conclusion by occluding the stomach and introducing the food through a pyloric fistula but even this experiment is not quite satisfactory since the retention of the stomach in the organism may modify, directly or indirectly, the chemical activity of the intestine, besides which the animals do not long survive so serious an operation. MM. Carvallo and Pachon, finding that the anatomical disposition of the stomach in the dog rendered that animal inappropriate for the operation of complete ablation of the stomach, determined to try the cat, and have satisfied themselves that for this particular experiment the cat is to be greatly preferred to the dog. Nevertheless, a large proportion of the cats operated on died, many from lung troubles the cause of which was at first obscure but which careful examination demonstrated to be due to septic infection proceeding from the points of suture. They were, however, able to present to the Société de Biologie a young cat from which the stomach had been entirely removed, and which had not only increased in weight three and a half months after the operation but was able perfectly to digest proteids in the form of cooked meats, starches, and fats. The digestion of raw meat was less perfect. They specially draw attention to the indisposition of both the dog and the cat to take the trouble of feeding themselves after the operation and they believe that the stomach plays an important part as a peripheral sensory organ.

THE STANDARDS OF PURITY FOR SEWAGE EFFLUENTS.

A TIMELY and valuable contribution upon this subject has recently been communicated to the Society of Public Analysts by Mr. C. G. Moor. The paper is all the more valuable because it shows that the writer possesses a practical experience of the subject and an ability to deal with both the chemical and bacteriological sides of the question. As he very properly remarks, purification of sewage so far as it is contemplated by any existing scheme can only be regarded as a chemical process, and it is in terms of chemical determination alone that the results of any process for effecting it can be expressed. Though we are learning now how great is the power of bacteria not only to purify but to utilise sewage, still the bacteria so involved are merely means for applying biological energy in place of the chemical energy previously employed, and are used for the precisely identical purpose of altering the sewage in its chemical composition from a substance highly favourable to the growth of putrefactive and some other organisms into a substance not specially favourable and perhaps ultimately inimical to their growth. Hence the corollary that the only terms in which a standard of purification for a process or a standard of permissible impurity in an effluent can be expressed, are necessarily and solely chemical. This does not depreciate the function of bacteriological examination, which might be directed to the determination of the extent to which effluents favoured or impeded the growth of undesirable organisms, and in particular those which directly cause disease and those which produce offensive organic substances. Such investigations cannot be without value in throwing light on the sewage purification by bacterial agencies, but, as Mr. Moor maintains, it is, after all, in quantitative terms of the chemical products which varying bacteria and varying conditions produce that the results of bacteriological investigation must be expressed before they pass over from the domain of experimental science into that of practical application. He accordingly suggests the following standard as satisfactory for general use: total suspended matter (not to exceed), 2·0 parts; albuminoid ammonia, 0·2 part; oxygen absorbed, 0·75 part; total hardness, 25·0 parts; and nitrogen as nitrates (not to be less than), 0·75 part per hundred thousand. Mr. Moor insists upon this amount of nitrates as showing that true purification has begun and that there is a store of oxygen which could be drawn on as a guarantee against possible putrefaction. We believe these figures are based on the analytical results of a great number of effluents which being within these limits are satisfactory, but obviously it would be difficult to make such a standard universally applicable. So much depends upon the nature of the sewage to be dealt with and as to the fate of the purified effluent. It might be satisfactory to discharge an effluent of a high degree of purity into a stream which is a source of supply for drinking purposes, while it would not be essential for an effluent to be so far purified when it is to be discharged on land or into a ditch. The suggestion to supplement the tests by observing the effect of the effluent upon live fish is, we think, an admirable one and one which, if it prove satisfactory, would be convincing of the innocuous character of the discharge.

THE OCCURRENCE OF THE TYPHOID BACILLUS IN THE EXCRETA.

THE July number of the *Medical Chronicle* contains the results of a research undertaken by Dr. J. R. Carver at the suggestion of Professor Delépine, its object being to obtain additional evidence as to the presence of typical typhoid bacilli in the fæces and urine of typhoid fever patients and if possible to suggest some explanation of the apparent disagreement of writers on the subject. The investigations were conducted in the bacteriological laboratory at Owens College and most of the material was obtained from the Monsall Fever Hospital, Manchester. He examined 16 specimens of urine and 20 of fæces all from separate patients presenting typical symptoms of enteric fever. In the examinations of the fæces inoculations of two or three loopfuls were made from the liquid stools into peptone bouillon, and this served as a stock tube. From this inoculations were made into tubes of phenylated bouillon (Parietti's solution) of various strengths. From these cultivations were made into ordinary shake gelatine plates,

Digitized by Google

while stroke cultures were made on potato gelatine. He afterwards adopted the method of direct inoculation from the stock bouillon tube into tubes of gelatine peptone bouillon which were then poured out into Petri plates. Some inoculations were also made on spleen gelatine prepared with fresh bullock's spleen. The result was that with the 20 specimens of fæces he found typical typhoid bacilli in only 2 cases. In 8 others he found a bacillus which gave some of the reactions both of the typhoid bacillus and of the bacillus coli and which he accordingly called the "intermediate" bacillus. In the 16 samples of urine he found only 1 colony of typhoid bacillus, and even this one was doubtful. On the other hand he found a coliform bacillus in 8 cases out of the 16. It was somewhat larger than the one usually found in the stools, but after some growths on agar they were indistinguishable and their reactions were similar.

THE NEW VACCINATION ACT.

A CIRCULAR has been issued from the Local Government Board to the clerks of the various boards of guardians pointing out that although the Act in its entirety does not come into force until Jan. 1st, 1899, the provisions of Section 2 became law on the passing of the Bill. This section contains the much-discussed conscience clause.

THE WORKMEN'S COMPENSATION ACT: A CIRCULAR LETTER TO THE MEDICAL REFEREES.

A CIRCULAR letter has been sent by the Home Office to the medical referees enclosing copies of the various official forms which will have to be filled up in the working of the Act and calling their attention to the dual nature of their duties. The first and most important function of a medical referee is to act as adviser to arbitrators or judges; but he has a second responsibility bringing him into relation with the injured workman rather than with any court or committee of arbitrators which it will require considerable tact and judgment properly to discharge. Schedule 1 (11) of the Workmen's Compensation Act runs as follows:—

"Any workman receiving weekly payments under this Act shall, if so required by the employer, or by any person by whom the employer is entitled under this Act to be indemnified, from time to time submit himself for examination by a duly qualified medical practitioner provided and paid by the employer, or such other person; but if the workman objects to an examination by that medical practitioner, or is dissatisfied by the certificate of such practitioner upon his condition when communicated to him, he may submit himself for examination to one of the medical practitioners appointed for the purposes of this Act, as mentioned in the Second Schedule to this Act, and the certificate of that medical practitioner as to the condition of the workman at the time of the examination shall be given to the employer and workman, and shall be conclusive evidence of that condition. If the workman refuses to submit himself to such examination, or in any way obstructs the same, his right to such weekly payments shall be suspended until such examination has taken place."

The Home Secretary in his letter reminds medical referees that he is not empowered by the Act to make any regulation as to the mode of carrying out this duty, but that care must be taken by the medical referee not to give the certificates in any circumstances other than those specified in the Act. The fee for the examination and subsequent certificate is payable not by the Treasury but by the workman himself, who, says the Home Secretary, "may be required to pay a reasonable fee before the examination is made"; but the referee is asked to remember in determining the amount of his fee that it is the workman who has to pay it and that only in some cases will he be able to recover it from his employer later. This second duty of the medical referee, if not so important as his main duty of acting as a judicial assessor, is certainly a very delicate one. He will be sitting in judgment, perhaps, upon the diagnosis of a professional brother.

MILK AND INFANTILE MORTALITY.

A PAPER by Dr. Lemière which is quoted in the *Journal de Clinique et de Thérapeutique Infantiles* discusses the relation long since recognised as existing between milk-supply and infant mortality. The statistics given are chiefly those of the city of Lille. Among other points of interest noted by the writer is the fact that the death-rate under two years of age in that city is 398·6, and in one parish it has risen to 520, for every 1000 deaths recorded. A large proportion of these is attributed to gastro-enteritis, which is most prevalent in districts inhabited by the working classes, the comparative mortality between a rich and a poor district selected for illustration being as 1 to 7. Gastro-enteritis is, as a rule, a preventable disease and this fact is fully admitted in the article to which we have referred. It is satisfactory to find that its explanation is sought for where it is most likely to be found—namely, in the diet administered. With regard to this Dr. Lemière makes two practical observations—one in which he accuses the employment of watered milk as a cause of malnutrition and the other in which he advocates efficient sterilisation and general care in feeding. Too much importance can hardly be attached to these remarks, especially during the present sultry weather. It is true that they teach nothing new, but they remind us of precautions which should never be but constantly are forgotten. We do not dispute the influence of subsoil water as a factor in the production of infantile diarrhœa, but we recognise as of equal and even greater importance the quality of the infants' milk-supply. The former consideration is in a great measure *ultra vires*, the latter is at all times within our control. If this control is applied with judgment and vigour the climatic and subterranean evils may often be entirely counteracted. Nothing, therefore, in domestic management is more important than care in the selection of the milk used and in its after-treatment. The health of the cattle producing it, of the people who sell it and the cleanliness of persons and vessels connected with its sale are as much the concern of a nurse or mother as is its actual preparation for the infant. As a rule mothers in this country understand the importance of cleanliness in all the manipulations of artificial feeding. Nevertheless they are frequently in error. They are very apt to under-estimate the value of fresh air, especially at night, and many an infant is poisoned with milk which has fermented in a close bedroom. We need hardly impress upon medical practitioners the necessity of instructing their patients in this matter and also with regard to the means adapted for the ready sterilisation not only of milk but also of the vessels in which it is contained and administered.

THE SILENT STRAND.

THE Strand without bustle and activity is no longer the Strand. By a ukase issued last week the Strand has been closed for traffic and sure and certain signs of the paviour coming along were evident to everybody by the accumulation of black wooden blocks upon the pavements of this thoroughfare. At the time of writing the Strand is "up" and those whose business is conducted within its precincts begin to enjoy a respite from vehicular clatter and also from sundry other street noises. The relief is perhaps most marked to those who, like ourselves, are engaged upon literary work. The appearance of the great historic street, however, in spite of its usual distracting condition, is somewhat depressing. One thing is

Digitized by Google

clear and that is that the biggest factor in the vehicular traffic is the omnibus, and this is essentially the vehicle which carries people to and fro through London's great artery. Despite the drawbacks which result from the congested condition of a street by the enormous traffic passing along in both directions there can be little doubt that this fact, after all, possesses a hygienic importance. The air of the Strand is now quite stagnant, an observation which has been made by a good many who use the thoroughfare. The lumbering omnibus is a big vehicle and in proceeding down a street pushes a volume of air in front of it, thus establishing an important degree of circulation. Hence the much-abused omnibus serves, so to speak, like a plunger in a cylinder chasing air in front of it and inducing fresh air to take its place. This process going on in both directions must have an important influence on the air of London's streets, for so narrow are some of our thoroughfares that the air is hemmed in, but the voluminous omnibus in its onward course tends to stir this up and to obviate stagnation. So we have an important compensation, perhaps, for the evils arising from the employment of animal power in our streets. Oddly enough, the hundred-and-one other street noises seem to have disappeared with the diverted traffic, except, however, that perennial curse the newspaper boy, whose irritating cries are more in evidence than ever, being untempered by vehicular noise. But we are no longer worried beneath our windows with a most exasperating toy which is regarded as imitating the utterance of chanticleer. People in the country know well that when this is produced by the bird itself it is sufficiently disturbing, but when the cry of the early bird is imitated on a toy it is almost beyond human endurance.

LAWLESSNESS IN THE STREETS.

ON August 8th Mr. Massey Mainwaring asked the Home Secretary a question concerning lawlessness in the streets and received the following typical ministerial answer :—

"I have received representations from the vestry on this subject, but after making inquiries I was not satisfied that there was any such insecurity as was alleged or such a condition of lawlessness that the existing force of police in the district were unable to cope with it. In certain districts there is doubtless more street rowdyism than in others, due to the general character of the population, but as far as the police are concerned active steps are taken by them to suppress any disturbances and to arrest offenders. The matter is, of course, of some importance, and I shall not lose sight of it."

It used to be said that nothing would be done to prevent railway accidents until a director or two had been killed. Are we to wait until a Home Secretary has been garrotted or knocked down and severely kicked before the police are given some more valuable weapon than a truncheon and are authorised to use it or until magistrates can order some more suitable punishment than a paltry fine which is always paid by a whip round of the prisoner's friends? The one and only remedy is the "cat"; it is cheap and efficacious. It did away with garrotting in the "sixties" and everyone will remember how Mr. Justice Day broke up the "High Rip Gang" in Liverpool by the use of the same means. Fines are useless, and prison is far too comfortable for Hooligans. Gymnasia and "education" may affect the budding Hooligan but not the full-grown plant. Since the Home Secretary's Epicurean answer hardly a day has passed without a case of violent assault being reported in the daily press.

THE ADULTERATION OF COFFEE.

ON reflection we should not think that the method of adulteration about to be described is "new," for it seems to us that it offers some explanation of the wooden character of the coffee infusions which are commonly offered to the public in this country. Coffee affords a most excellent beverage, but nobody seems to be able to get it good, and this is probably the reason why the consumption of coffee is rapidly declining. But the material must, of course, be good and fresh, with all the aromatic oils preserved intact. We have heard that by coating the roasted berries with a thin film of gelatin the delicious aroma of freshly roasted coffee may be indefinitely preserved. But this step would be quite futile in view of the "new" adulteration. This consists in washing, colouring and drying the berries in centrifugal machines with sawdust, with the result that the crevices of the berries become filled with powdered wood which is said to make them of a fine white colour, and thus to enhance the market value of the product. This ingenious but immoral process is said to be carried on in Hamburg, Bremen, Antwerp, and Rotterdam, and we respectfully request our Customs authorities to keep a sharp look out on the consignments of coffee coming from these places in spite of the market value, as it is said, being thus enhanced.

THE DENTAL HOSPITAL OF LONDON.

WE are pleased to learn that the difficulties which have for some time hampered the action of the Committee of Management of the Dental Hospital of London have been overcome and that the contract with the builder for the new hospital is now signed. The building is to be finished in twenty months, and the fact that definite arrangements have at last been made must be very satisfactory to Lord Kinnaird and Mr. F. A. Bevan, the trustees, and Dr. Joseph Walker, the honorary treasurer, who have worked very hard to attain this end. We hope that the public will help forward the work by donations and subscriptions. So far the dental profession has contributed £7000 and the public about the same amount, while some £30,000 are still required to discharge the liabilities incurred. The Dental Hospital has a distinct claim on public generosity over and above the value of its work. Mortgage had to be incurred when the buildings on the new site were demolished two years ago by the order of the London County Council, while the hospital lost a revenue of £1200 a year, which sum the Committee of Management intended should accrue to help to pay for the new building.

NEW MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

WE are informed that the two temporary medical inspectors to the Local Government Board who were sanctioned under the report of the Treasury Committee of August, 1897, have at last been appointed. The difficulties which have caused such long delay have been owing firstly to the fact that a permanent increase of work called for permanent and not temporary appointments, and secondly to the circumstance that when the appointments were at last offered it was naturally found that some of those nominated could not abandon permanent posts which they then held for the sake of temporary ones. At last, however, all difficulty has, for the moment at least, been removed. Dr. L. W. Darra Mair, the well-known medical officer of health of the Croydon Rural District, has obtained one year's leave of absence from his duties in order to accept one of the posts in question. The other post has been conferred by Mr. Chaplin on Dr. Ralph W. Johnstone. Both of the new inspectors hold the Diploma in Public Health.

A TELEGRAM from Hong-Kong was received on Monday morning last by the Colonial Office reporting that only one case of plague occurred last week.

Digitized by Google

A FORTNIGHT ago it was our sad duty to offer our sympathy to Mr. Henry Power in his sorrow and to-day we are reluctantly compelled to recount another terrible accident affecting a prominent member of the medical profession—namely, Sir Walter Foster, M.P., whose daughter while bathing at Woollacombe, near Ilfracombe, was carried away by a wave and drowned. While offering our sincere condolences to Sir Walter Foster we feel obliged to remind the local authorities that this is by no means the first case of drowning off the foreshore which has occurred in this district, and we think that better precautions should be taken to ensure the safety of bathers, although it is said that the cove where the accident happened is not a recognised bathing place.

DR. GEORGE ROPER, whose death occurred at Southwold on Sunday last, August 14th, was at one time physician to the Royal Maternity Society. We hope to publish a few notes on his life and scientific career in an early issue.

WE have received Dr. Whitelegge's report for the year 1897 as chief inspector of factories. We shall deal with the report in an early issue, as it is made specially interesting by the new Workmen's Compensation Act.

WE shall publish next week the concluding article of Dr. Lionel Beale's series entitled "Vitality."

PLASTER MODELLING: A DEMONSTRATION BY MR. G. A. PETERS, F.R.C.S.

ON Wednesday afternoon, at the Examination Hall, Victoria-embankment, an interesting demonstration of an original and improved method of making plaster-of-Paris models of anatomical and pathological specimens was given by Mr. George A. Peters, F.R.C.S. Eng., of Toronto. The process consists of a rapid method of making a paraffin mould from which a finely-detailed and sharply-defined plaster-of-Paris cast of the specimen can be readily produced.

The mould is obtained by means of an ingenious spray devised by Mr. Peters, the apparatus consisting of two tin reservoirs, one being a simple can containing iced water and the other a can constructed with an inner and an outer compartment so arranged that paraffin placed in the inner compartment can be kept in a molten condition by a jacket of hot water in the outer one, each reservoir being connected by rubber tubing to a double-channelled spray nozzle, the conduit for the paraffin being completely jacketed by an outer tubing containing hot water. The spray is produced by a strong current of air generated in an ingenious pressure air-pump by electromotive force. By means of this mechanism a fine spray of pure paraffin can be instantly produced and its flow readily regulated by means of an adjustable nozzle.

The specimen demonstrated upon by Mr. Peters was a dissected guinea-pig, and the *modus operandi* was as follows. The paraffin reservoir was charged with paraffin having a melting point of about 125°F. and the other reservoir with iced water. The specimen, placed on a mackintoshed dissecting board, was first lubricated with a spray of alboline to prevent adhesion to the paraffin, the hairy regions for the same reason being also sprayed with an alcoholic emulsion of corn-flour. The paraffin spray was then put in action by switching on the electric current and a fine spray of pure paraffin was directed upon the dissected specimen, which was quickly covered with an even coating of the paraffin which immediately solidified on coming in contact with the surface of the specimen. The next stage was the application of a strong mixed spray of paraffin and iced water, which had the effect of accelerating the building up of a thick casing of firmly set paraffin. Over this a stiff paste of plaster-of-Paris, to which a watery solution of sulphate of potash had been added to promote setting, was spread to strengthen the mould. A few minutes were then allowed for the plaster to set, after which the cadaver was removed from the paraffin and the mould was ready for use.

Mr. Peters then showed several models which he had produced by this method, among them being a fine plaster cast of Dr. Sims Woodhead's head, a model of Professor Cunningham's hand obtained at the recent meeting of the British Medical Association at Edinburgh, and a model of a dissected guinea-pig obtained from a mould similar to the one made during the demonstration, which showed the fine anatomical features in minute detail, even to the blood-vessels of the mesentery. Other models were also demonstrated as examples of the applicability of the method to the modelling of furred animals and birds, the lecturer incidentally mentioning that a complete model of a living head could be obtained in about twenty minutes.

Among those present at the demonstration was Sir William Mac Cormac, President of the Royal College of Surgeons of England, who at the conclusion of the proceedings cordially thanked Mr. Peters for his demonstration and heartily congratulated him upon the excellence of his results.

ANNUAL REPORT OF THE METROPOLITAN ASYLUMS BOARD.

SECOND NOTICE.[1]

Medical Supplement.

THE medical staff of the Metropolitan Asylums Board includes many highly qualified men both as medical superintendents and as assistant medical officers, and it is of considerable importance that this should be the case since the circumstances of a fever hospital are very different from those of a general hospital. In this latter the visiting staff of leading physicians and surgeons guide and advise the resident medical staff, while in addition there is the stimulating influence of competition and publicity ever present. In the fever hospital, on the contrary, these influences are to some extent absent, and the institution is in large part self-contained. It is true that within recent years the admission of students into these hospitals has done something to modify this self-contained element; but nevertheless the officers are, by the very nature of their occupation, cut off in some degree from the outside world. It is for this reason, amongst many others, that we welcome the new departure which, commenced in the annual report of 1896, has become developed in the report for 1897 which is now before us.

The Statistical Committee have very wisely relinquished the task of editing the purely medical part of the report and have left it, we trust entirely, in the hands of the medical staff of the fever hospitals, who have appointed two of their colleagues, Dr. Caiger and Dr. Goodall, to edit the "Medical Supplement." We do not know precisely what is the method of compilation adopted; whether, for instance, certain members of the medical staff are invited each year to take up some subject and after having studied it to report thereon, or whether the contributions to the supplement are left in the main to the initiative of the medical officers and the revising control of the editors. But in all probability a judicious blending of these two methods is encouraged. Be this as it may, we welcome the supplement as a valuable innovation and as affording a great inducement to the medical staff to make more use than has been, perhaps, made in the past of the altogether exceptional opportunities afforded to them. It is to be hoped, too, that the committees of the several hospitals will themselves recognise the importance of encouraging original research amongst the medical staff and this they may do by satisfying themselves that the members of the staff are in no sense overworked. A medical attendant whose whole time is taken up in admitting cases and in attending too large a number of patients is not likely to be of the greatest use to the patients or to make the careful notes and observations calculated to add to our knowledge.

In the present supplement Dr. F. F. Caiger deals with the subject of complications and of the coexistence of infectious diseases as illustrated by the statistics of all the hospitals

[1] The First Notice was published in THE LANCET of August 13th, 1898.

Digitized by Google

during 1897. On the 15,241 cases of scarlet fever the incidence of otitis was 14·39 per cent., of albuminuria 8·87 per cent., of the adenitis of convalescence 5·59 per cent., of rheumatism 3·32 per cent., and of nephritis 2·80 per cent. Relapse occurred in 0·72 per cent. of the cases, diphtheria in 5·22 per cent., and varicella in 3 49 per cent. Among the 5493 cases of diphtheria albuminuria occurred in 42·19 per cent. and paralysis in 20·55 per cent., while 6·99 per cent. suffered from scarlet fever. In enteric fever 13·06 per cent. of the cases had a relapse, 9·9 per cent. hæmorrhage, 3·10 per cent. perforation, 2·4 per cent. pneumonia, and 1·9 per cent. non-perforative peritonitis. Among the 21,400 cases of infectious disease admitted into the Board's hospitals for acute infectious disease no less than 596, or 2·78 per cent. of the total admissions, were suffering on admission from two separate infectious diseases. By far the greater number suffered from a combination of scarlet fever and diphtheria, scarlet fever and varicella and scarlet fever and whooping-cough being the other associations most frequently met with. Those of our readers who take interest in this subject of the coexistence of infectious diseases in the same individual will find a very complete paper on it, also from the pen of Dr. Caiger, in vol. xiii. (new series) of the Transactions of the Epidemiological Society.

The incidence during 1897 of post-scarlatinal diphtheria on the 15,241 completed cases of scarlet fever amounted to 5·22 per cent., or 0·58 per cent. above that of last year. Dr. Goodall is careful to point out that the bacteriological examination of all suspicious cases has probably had considerable effect in bringing about this high incidence rate, and for this reason it would, he adds, be unsafe to compare the incidence on hospital treated cases with that upon the home treated cases. The total fatality-rate of the post-scarlatinal cases was 3·7 per cent., that of the laryngeal cases 3·7 per cent., and of the remainder 2·9 per cent. In 1896 the three rates just given were respectively 5·1, 22·7, and 2·8; and it will be seen that an enormous reduction has been made on the laryngeal cases. As regards the onset of these post-scarlatinal attacks of diphtheria the majority occurred during the fifth and sixth weeks following the onset of the scarlet fever, and the greatest percentage incidence of the disease was during the first and third quarter of the year. The figures for 1897 do not, Dr. Goodall thinks, shed any fresh light on this question of post-scarlatinal diphtheria, and he is evidently inclined to regard the increase within recent years as but an expression on hospital treated patients and the increased incidence of diphtheria on the population as a whole. It is, in a way, unfortunate that we cannot institute any satisfactory comparison at present between the home treated and hospital treated cases in this particular, as we might in course of time learn something from such a study. Obviously, the question is whether there is an *undue* incidence on hospital treated cases.

Coming now to the results of the antitoxin treatment of diphtheria during 1897 we find some encouraging figures which show improvement upon those for 1896. Of the total number of completed cases (5459) 80·2 per cent. were treated with serum, as against 66·2 in the previous year, and of the serum treated cases 20·4 per cent. died, as compared with 25·9 per cent. in 1896. In the laryngeal cases the fatality-rate was 30 per cent.; in the cases upon which tracheotomy was performed 39·9 per cent. In the year 1894—that preceding the introduction of antitoxin—the fatality-rate of all cases was 29·6, of the laryngeal cases 62 per cent., and of the cases on which tracheotomy had been performed 70·4 per cent. Perhaps, however, the best index of the valuable results of antitoxin is to be found among the post-scarlatinal cases of diphtheria occurring in hospital which have naturally a high fatality-rate, but which being easily recognised can be subject to antitoxin treatment at once.

Most of the other contributions to the "Medical Supplement" are, we presume, from the assistant medical officers, whom we are glad to see contributing their share; indeed, these officers have, perhaps, a better opportunity for original work than have the medical superintendents, no small portion of whose time must of necessity, if they are to govern the hospital in a satisfactory manner, be taken up with important administrative duties. Dr. Arthur Stanley's paper on the Condition of the Heart in Diphtheria is of a high degree of merit and betrays considerable observation and care at the bedside. He finds, too, that in persons dying from that terrible complication of diphtheria, cardiac paralysis, very distinct signs of degeneration are constantly found in the cardiac muscles, while he has been unable to demonstrate anything abnormal in the "immediate extra-cardiac nerves or nerve endings." Dr. A. Miller's contribution on the date of onset of the various forms of diphtheritic paralysis follows appropriately the foregoing. Of 392 cases paralysis appeared first in the palate in 185, and in the ocular muscles in 197. In the remaining 10 it commenced elsewhere. Of 102 cases of cardiac paralysis no less than 91 proved fatal. Dr. Richards and Dr. Goodall describe a case of enteric fever where an endeavour was made to counteract the effects of an intestinal perforation by laparotomy and suture of the gut, and the result, though ultimately fatal, is by no means discouraging.

Of the other papers we have space only to refer to that by Dr. R. G. Kirton on the Serum Diagnosis of Enteric Fever. He feels as a result of his observations (1) that "Widal's reaction" is usually obtained in cases of enteric fever, whether they be mild or severe, but that it is not obtained from cases suffering from other diseases, unless perhaps in those who have recently recovered from enteric fever; (2) that this reaction is obtained earlier in some cases than in others (three cases gave the reaction only on the second attempt); (3) that the blood retains its power of yielding the reaction for a variable time—it may be for a few months, perhaps for some years; and (4) that the blood taken after death from a case which has yielded the reaction during life may still continue to react.

A PATENT FOR DIPHTHERIA ANTITOXIN RECENTLY GRANTED IN THE UNITED STATES.

PROFESSOR BEHRING'S action in applying for a patent in the United Sates as sole inventor of diphtheria antitoxin excited surprise, but the announcement that the authorities at Washington have recently decided to grant the patent has caused a feeling of something like consternation among the American manufacturers of antitoxin. The medical profession too are up in arms against Professor Behring's departure from recognised professional ethics and many of the medical journals condemn in strong terms his unaccustomed mode of procedure. It was in January, 1895, that Professor Behring—his assignees being the Höchst-Farbwerke, the manufacturers of the serum in Germany—first applied for a patent for his diphtheria antitoxin; the application was then refused and has been refused four times since on the apparently substantial ground that Professor Behring was not the sole inventor of diphtheria antitoxin and had consequently no right to claim a monopoly of the manufacture and sale of the same. However, in June last the patent officials at Washington overlooked their objections and granted the patent, not because they thought that Professor Behring had established his claim by right of priority or by originality in research, or even on legal grounds, but for the sentimental consideration that the treatment of diphtheria by antitoxin had yielded such satisfactory results and had greatly decreased the death-rate from this disease. This altogether unexpected decision on the part of the United States Patent Office has given universal dissatisfaction amongst both medical men and manufacturers of antitoxin throughout America, as it is contended that it is neither logical nor just. Its opponents assert that before granting the patent positive proof should have been forthcoming that Professor Behring was undoubtedly entitled to the credit of discovering the principle of serum immunisation and of inventing diphtheria antitoxin and that to grant a patent for any other reasons was absurd as well as unfair to those scientific men who assisted in the successful development of serum therapy. Among the American papers which contain articles deprecating alike the action of Professor Behring in applying for a patent and that of the Patent Office in granting it, *Pediatrics* of August 15th, in its editorial comments, perhaps treats the subject most exhaustively from the point of view of the medical profession and of the manufacturers. Referring to the question from a scientific standpoint the above-named journal says: "We will first consider the matter from a scientific standpoint and endeavour to show that although without doubt

Digitized by Google

to Behring is due the chief credit for developing serum therapy, yet that this development has reached its present successful issue by progressive stages to which many earnest workers have contributed." A short sketch is then given of the discoveries of Salmon and Smith in 1886, Pasteur, Roux, Chamberland, Fox, and Bonhomme in 1887, and Frankel in 1890, tending to prove that much progress had been made in the development of the principle of serum immunisation before Behring and Kitasato published their results. *Pediatrics* concludes that Pasteur was undoubtedly the discoverer of the principle of serum immunisation, while to Roux and Aronson belongs the merit of first putting the serum to clinical uses, and comments on the fact that the French Academy of Sciences was so undecided as to which of the respective claimants was entitled to the credit of the invention of diphtheria antitoxin that they concluded that both Roux and Behring were equally deserving and awarded the prize jointly. Dealing with the ethical side of the question the same journal remarks: "Since Jenner introduced vaccination for the prevention of small-pox and thus rendered his name immortal there has been no discovery made in the realms of science more valuable than the principle of serum immunisation and no invention more efficacious in relieving and curing human disease than that of diphtheria antitoxin. ..... Although, as we have pointed out, no one man can lay claim with justice to the honour of the discovery for himself alone, nevertheless Behring has probably accomplished more than any other worker in the establishment of serum therapy. To him, too, has been accorded by far the largest share of the accompanying fame and it may be said that if he had not made this unfortunate departure from the accepted code of professional ethics his name would have been handed down to posterity linked with those of Jenner, Lister, and Pasteur. By his selfish attempt, however, to reserve to himself and the company with which he is connected the right to manufacture and profit by the sale of diphtheria antitoxin he has besmirched his reputation and lowered the dignity of the profession to which he belongs. That many of the pioneers in science do not reap a fair share of the harvest sowed and brought to maturity by the efforts of their brains and that they are often used as ladders by which unscrupulous men of superior business capacity ascend to position and fortune cannot be denied. A discoverer or inventor is most assuredly entitled to an ample portion of the rewards resulting from the success of the child of his intellect and we are certain that no one would begrudge Professor Behring the highest possible pecuniary rewards, but at the same time we cannot but think that by placing an invention of the nature of diphtheria antitoxin within the category of a patent medicine and by attempting to create a monopoly of a discovery which belongs by right to the whole human race he has deviated from the best traditions of scientific ethics and has pursued a course which he will live to regret." After making a brief reference to the spirit of commercialism prevailing in Germany at the present time *Pediatrics* ends by regretting that the patent laws of the United States are so criminally lax and says: "Before leaving the subject of Behring's patent it may be as well to make a few remarks in regard to the patent laws of this country. The fact is well known that any like application would meet with prompt and final refusal in every other country of the world. Indeed, no sane person would have the simplicity to apply for legal protection for an article of the nature of antitoxin in any land but the United States, convinced beforehand that the attempt would be useless. In France and Germany so strict and exclusive are the patent laws that even foods and medicines save on processes of manufacture cannot be protected. Does it not therefore seem an absurdity and injustice as well as a slur on the proverbial American cuteness that foreigners are allowed to enjoy privileges here which they are unable to obtain in their own countries? It should also be borne in mind that in this respect 'they manage things better on the other side.' We are too apt to think that all our institutions are superior to European ones, but there can be no doubt but that in matters of this kind we are far too lax and might with benefit to ourselves take a leaf from the book of our German and French friends. Reform in our patent laws is urgently called for." Although Professor Behring has succeeded in gaining a patent for his diphtheria antitoxin it is the intention of the American manufacturers of antitoxin and the several boards of health to contest his right to create a monopoly at every step.

THE SPREAD OF DISEASE THROUGH LAUNDRIES.

IN THE LANCET of August 18th, 1877, we published a report of a Special Commission on the Spread of Disease through Laundries. We then demonstrated in so conclusive a manner how linen was contaminated, more especially during the process of ironing and drying after washing, that the Press of the entire country took up the question. So much alarm was occasioned by this discussion that in the course of a few weeks five companies were founded so as to establish sanitary laundries in which the dangers which we had denounced might be avoided. Since then many other similar enterprises have been started and in almost every important centre in England there are one or more laundries which at least profess to wash linen on sanitary principles. We very much doubt whether the precautions which these establishments profess to take are always efficient. Still, it is a step in the right direction to find that the necessity of precaution is widely admitted. The agitation thus started in England has travelled abroad and in Paris and Berlin notably there are several large hotels which make it their boast never to give or to allow linen to be given out promiscuously to be washed. These establishments have their own steam laundries where the linen washed cannot come into contact with any outside linen. In a general way, however, the problem has been considered in France from the point of view of the laundresses themselves rather than from the standpoint of the public at large. During the recent prevalence of cholera in Europe several epidemics originated in laundry establishments and the first victims were washerwomen. Subsequently, at a sitting of the Paris Municipal Council held on Nov. 15th, 1896, M. Marsoulan brought forward the question of laundries and the diseases which laundry women contracted by manipulating foul linen. The council adopted a resolution in favour of studying the means which might be taken to mitigate this danger. Following upon this Dr. G. Deschamps, Médecin Inspecteur du Service des Epidémies, was appointed to draw up a report on the subject. On its side, the Council of Hygiene and Salubrity of the Department of the Seine, in its sitting held on Oct. 29th, 1897, elected a Commission consisting of Dr. Proust, Dr. Yangfleisch, Dr. Brousse, Dr. Le Roy des Barres, Dr. Dagnet, and Dr. Vallin to likewise investigate the matter. Dr. Vallin was the reporter of this Commission and he concludes in his report that laundresses obviously run considerable risk of contracting infectious fevers from the dirty linen. Where compulsory notification and disinfection for such complaints is strictly enforced this risk is of course in a great measure dissipated. But it is also acknowledged that there are still some families who conceal the presence of infectious disease. Though in Paris such linen would be disinfected gratuitously, still there are persons who will not apply to the sanitary authorities: they fear that the linen may be spoilt in the process of disinfection or it is so dirty that they are ashamed to show it.

At first linen soiled with blood, &c., was undoubtedly spoilt by the process of disinfection. The heat, by coagulating the albumin, fixed the colouring matter and the linen was permanently stained. But now, and indeed for some ten years past, all linen thus stained is rinsed and brushed before it is placed in the disinfecting stove. Dr. A. J. Martin, Inspector-General of this service, states that this preliminary operation is carefully supervised and quite successful both from the point of view of preventing stains and of preventing infection. But even if in regard to the more serious infectious diseases proper precautions are taken, there remain cases of measles, tuberculosis, septic suppurations, blennorrhagic discharges, syphilitic secretions, and premonitory diarrhœa, for which no notification is sent to the sanitary authorities and disinfection is not enforced.

The most dangerous operation is the sorting and marking of the linen before it is washed. In large model laundries this is, or at least it should be, done in a special separate department, room, or shed. But even then the germs are disseminated, infect the persons who sort the linen, and may be conveyed to some distance by the wind. Dr. Vallin suggests that the dirty linen might be sorted under an antiseptic spray. At the same time he doubts whether the laundresses

Digitized by Google

would give themselves the trouble to take these precautions properly. In some large model laundries there is an automatic disinfecting washer. It consists of a revolving perforated case inside a cylinder. This case or drum is divided into several compartments. In each compartment a bundle of dirty linen as received from the customer is introduced without being sorted. The apparatus is now closed, the case made to revolve, and a current of cold water discharged upon it so as to remove the blood-stains, and this is followed by tepid water. When this has been done the linen can be purified by boiling water or jets of steam under pressure, the heat varying from 110° to 120° C. It is only after this process is terminated that the linen is taken out and sorted. Such an operation certainly reduces the risk to a minimum. The report of the Commission of the Council of Hygiene concludes by recommending that every effort should be made to induce families to send their linen to the public disinfecting stations, where it will be purified gratuitously and in no wise injured. Then it is urged that all dirty linen should be conveyed in air-tight special sacks, that the linen should be sorted under an antiseptic spray in a separate and special place or shed, and that in large laundries there should be a special apparatus for blood-stained linen where it can be soaked in tepid alkaline water before it is sorted.

Dr. E. Deschamps, in his report, deals particularly with the smaller laundries and the practical difficulties in the way of effective reform. He points out that in spite of the danger of infection to which they must be constantly exposed pulmonary tuberculosis is comparatively rare among washerwomen. This raises an interesting question as to whether this immunity is due to the deterring effect which the dampness prevailing in laundries may have on the tubercle bacillus or whether it arises simply from the fact that laundry-women must possess a certain amount of physical vigour to do their work. With regard to infection through linen amongst the poorer classes in Paris, many women wash their own linen, and if there is infectious disease in their family this operation does not add considerably to the danger to which they are already exposed. Others get their linen washed by a friend and neighbour who would certainly know if there was any illness and could take precautions. The greatest danger arises with the lower middle classes, who give out their linen to small laundry establishments in the immediate neighbourhood. In that case it is generally the mistress and not the servant who sorts and gives out the linen. The mistress would very likely conceal the fact that some member of the family was ill fearing that the laundress might charge extra for washing the linen on the ground that special precautions had to be taken. The linen is taken probably to a very small laundry shop in a crowded thoroughfare; it is sorted in the same room where later in the week it will be folded and ironed. These small laundry shops must be centres of infection and to expose clean linen in such places is certainly dangerous. On the other hand, to classify them as unwholesome industries and to decree that no linen shall be washed except in a large model laundry would throw out of employment an enormous number of very worthy people and make all laundry work a monopoly held by a few large capitalists.

Another point raised is the danger to the public due to the fact that linen stained with blood, pus, &c., must, first be soaked in cold or in tepid water. What becomes of this water? It must often contain pathogenic germs. In certain localities it may be a fruitful source of river pollution. The best protection, according to Dr. Deschamps, will be the strict enforcement of compulsory notification and disinfection in all cases of infectious disease. In this respect we are more fortunately situated in England, where both law and custom favour this practice. Nevertheless, the law is still too frequently evaded and, as already pointed out, there are cases which do not come under its provisions. Both Dr. Vallin and Dr. Deschamps repose far too much confidence in the effect of compulsory disinfection. Such laws as they desire are in force in England and were in force when our report on the spread of diseases through laundries was published. Nevertheless, we clearly demonstrated how linen was set out to dry close to cases of small-pox and that the law was constantly evaded. The only radical remedy is the abolition of pettifogging laundries. A private dwelling or a small shop in a street is not a place where a laundry business can be carried on under safe and wholesome conditions. On the other hand, and so that the trade should not be monopolised by large capitalists who alone can build model steam laundries, public washhouses should be so constructed as to serve the same purpose. Here those who do washing on a small scale should find all the necessary conveniences and be made to carry out those precautions which are best calculated to protect them and their customers from the danger of infection. The French reports confirm our report and show that laundry work as a home industry cannot be carried out safely. But the French reports only utilise this fact as an argument in favour of compulsory notification and disinfection wherever there is a case of infectious disease. This we are convinced will not suffice, and as we are, like our French colleagues, anxious not to ruin laundresses who have only small businesses we repeat that these small businesses should be transferred to improved public washhouses. In the meanwhile the most practical result of the reports published by the Paris sanitary authorities is a more extensive use of air-tight sacks in which the dirty linen is conveyed.

Public Health and Poor Law.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Halifax Urban District.—An instructive little milk-borne epidemic of scarlet fever occurred in this district in 1897. A sudden excess of notifications of this disease having been observed inquiries were set on foot as to the cause. All who were affected were found to be deriving their milk-supply from one or other of two purveyors, one being merely a dealer, the other a farmer who supplied milk directly and also through the dealer. At the house of the dealer no clue was discovered, but on visiting the farmer Mr. D. Ainley (the medical officer of health) found a boy with a well-developed rash and sore-throat moving freely about the premises and amongst the cows. The farmer himself was in bed with a sore-throat and his wife showed signs of desquamation, while an elder son, aged nineteen years, who took the milk into the town, had also a sore-throat. It was arranged that the milk should have no connexion with the farmhouse or with the infected persons, but it was not under the circumstances thought necessary to prohibit the supply. A list of customers was obtained from the two purveyors and the medical officer of health visited every one of them. By this means a considerable number of cases was discovered. It is to be inferred that the potency of the milk for harm was removed when the sources of infection were cut off.

Northamptonshire County District.—We heartily welcome the appearance of this, the first report of Mr. C. E. Paget, the first county medical officer of Northamptonshire. Mr. Paget, whose interesting reports on the health of Salford we have noticed for many years, only took up his new duties on Jan. 1st, 1898, so that, as he tells us, he knows little from personal observation of the sanitary condition of the county. The annual reports from the district medical officers of health were sent in with promptitude, but, as has been the case so frequently before when a county medical officer has entered on his duties, only four of those relating to the urban and six to the rural districts were printed. Doubtless, however, Mr. Paget will soon effect a change here. The estimated population of the county is 228,955, 99,878 of whom are living in urban districts. The birth-rate of the administrative county during 1897 was 29·5 per 1000 (urban rate 33·4, rural 26·4); the general death-rate was 15·5 (urban 14·7, rural 16·09). The infantile mortality for the county was 134 per 1000 registered births (urban 142, rural 125). Several of the sanitary districts are without the benefits of notification, and amongst these we notice the borough of Brackley, while some eighteen districts are without any hospital provision and others have it only "by arrangement." In short, Mr. Paget has an admirable field for his energies, and we shall watch the progress of the county with interest.

Huddersfield Urban District. — In investigating the circumstances attendant upon certain cases of puerperal fever notified to him during 1897 Mr. E. G. Annis, the medical officer of health, states that on visiting the midwife's home he generally finds the conditions "absolutely indescribable; evidences of neglect, dirt, filth, and a general squalid condition abound." He points out that about one half of the children born in Huddersfield are introduced into

Digitized by Google

the world by midwives and he thinks it very necessary that some control over these women should be exercised. He has done well to call attention to the condition of their homes. New regulations as regards cowsheds, dairies, and milk-shops have been recently brought into operation in Huddersfield, a minimum of 500 cubic feet being the allowance for each cow. It is further suggested that every cowkeeper shall arrange with a veterinary surgeon for the periodical inspection of the cows. We also note that "no milkman with his can should on any account enter the houses of his customers."

Birkenhead Urban District.—The inhabitants of this borough will hear with satisfaction, in face of recent outbreaks of water-borne diseases, that their water-supply "is of exceptional purity and altogether most satisfactory from the public health point of view." It is obtained from the new red sandstone at three separate pumping stations, the average depth of the wells being 207 ft. The supply yields 17 gallons per head per day. Some interesting figures relative to tuberculosis in edible animals are furnished by Dr. Sydney Marsden in his report. Of 3655 cattle slaughtered in the Tranmere abattoirs from 1892 to 1897, 82 were affected with tuberculosis; and if we read the tables correctly, nearly the whole of those thus affected came from Cheshire and Wales. Of 4174 pigs killed, presumably in 1897, 57 had tuberculosis; but of 10,500 sheep and lambs slaughtered during the same period not one was thus affected. Of 626 calves killed 3 had tubercle. Out of 241,717 cattle *inspected* at the Woodside and Wallasey lairages during 1897 113 were affected with tuberculosis; 12 of these came from the United States, 18 from Canada, and 83 from South America. As an instance of the difficulty found in practice in carrying out an improvement scheme for the housing of the working classes we may refer to the case of Birkenhead. In 1896 a provisional order relating to the area in question was confirmed by Parliament, but up to the date of the issue of the report now before us not a stone had been touched.

Nottingham Urban District.—Amongst the Jubilee honours of 1897 the town of Nottingham occupied no mean position, and the bestowal on it by Her Majesty of the title of "city" evidently gave much justifiable satisfaction to the inhabitants. Despite the advance which has been made in the sanitation of Nottingham within recent years there are still, Dr. Boobbyer tells us, no less than 40,000 pail-closets to be dealt with, and he regards the danger to health from these receptacles as but little less than that from privies. As he points out, it is the abuse to which the pail is liable which in the main reduces it to a condition little better than the privy. As to the incidence of enteric fever in houses supplied respectively with privy, pail, and water-closet the figures presented by Dr. Boobbyer in his last report and repeated in the one now before us are well worth quoting. He found that for the years 1887–96 the figures yielded the following incidence of enteric fever. Midden-privy houses, 1 case in 37 houses; pail-closet houses, 1 case in 120 houses; water-closet houses, 1 case in 558 houses. He also supplies other figures in reference to these classes of houses tending to show that the danger of infection from a given case of enteric fever is much greater in privy and pail-served houses than in those with water-closets, while the risk of the recurrence of the disease is also greater. It is important to mention that the water-closets are scattered promiscuously amongst those of the conservancy type and hence no question of locality or class distribution is sufficient to account for the differences observed. In connexion with the Bagthorpe Isolation Hospital there were 14 "return" cases of scarlet fever and certain of these may have owed their origin in some way or other to 10 discharged patients. The average duration of stay in hospital had been over 12 weeks and we do not gather that any of the patients were suffering from chronic discharge. Isolation accommodation has been provided during the year for cases of enteric fever and good results seem to have been attained thereby. In an appendix to his report Dr. Boobbyer gives the report of a deputation of the sanitary committee which he accompanied to Essen and Cologne for the purpose of inspecting certain knackeries and abattoir buildings there. As Dr. Boobbyer aptly remarks, the report shows "that our rivals of the Fatherland spare no trouble and expense in safeguarding their meat supplies and organising upon the most sanitary and economic bases the very numerous subsidiary industries arising in connexion with their preparation."

Bristol Urban District.—In November of last year the limits of this city were so extended as to embrace a population of 318,042, but the statistics of the present reports, which are illustrated by means of a series of very clear diagrams, relate to the old population of 232,242. Bristol is apparently much to be congratulated upon its water-supply, despite the fact that the supply is in the hands of a private company. The water, according to Dr. Davies, "appears to be above suspicion" as regards its risk of excremental contamination. The bacteriological examination of cases of diphtheria and the application of Widal's test for cases of enteric fever are still pursued at Bristol, and we trust they will be continued. It is, however, easy to understand what a heavy task this laboratory work must entail upon Dr. Davies, more especially in presence of the increased work and reponsibility which the added area and the appointment of five additional inspectors must involve. It is to be hoped that this necessary bacteriological work will be provided for and that it will not be allowed to drop. Dr. Davies does not advise any alteration as regards sewer ventilation in Bristol. Our readers may remember that the Bristol sewers are not ventilated. Such ventilation can, he observes, be asked for either to prevent danger to health or to prevent nuisance, and there are no indications, he thinks, for action in either direction. He regards the "suggested danger of 'fever' outbreaks from the unventilated condition of the sewers as purely chimerical." In referring to small-pox a note of warning as to isolation accommodation is uttered. It is pointed out that it is the generally well-vaccinated condition of the infantile population which renders isolation possible as a controlling factor in small-pox, but were Bristol an unvaccinated town—and we fear that it is tending to become so—a thousand beds would, Dr. Davies observes, soon become full and what would be practically chaos would reign, assuming that small-pox of an epidemic type were to invade the city. There is included in the volume before us the report which Dr. Davies made upon the Clifton outbreak of enteric fever in 1897, but as this outbreak has received considerable publicity already it is hardly necessary to refer to it further here. A paper upon it was read before the Epidemiological Society. We are very glad to see that Dr. Davies has had "Bristol Health Report, 1897," printed on his report in such a fashion that it can be read when the volume is placed on the bookshelf. It would save some time and trouble to us if all volumes of sufficient size were treated in a similar fashion.

Croydon Rural District.—Considerable activity in respect of sanitary matters has obtained during recent years in this district under the judicious guidance of Dr. Darra Mair and the report for 1897 shows that great progress is being made. In referring to diphtheria the importance of notifying mild cases is insisted upon and it is pointed out that the proximity of this district to the metropolis involves frequent fresh introductions of the disease. In dealing with cases of this malady precautions are, as a rule, continued until the throat has been demonstrated to be free from the bacilli associated with the disease. We note that two persons were bitten by rabid dogs during 1897 and on both occasions the patients were despatched to Paris for treatment at the rural district council's expense. In connexion with the prevention of river pollution improvement is manifest and we see that an endeavour has been made to prevent the sale of watercress which has been grown in, or washed by, the effluent from the Croydon sewage farm—a precaution which will doubtless meet with approval.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7055 births and 4410 deaths were registered during the week ending Aug. 13th. The annual rate of mortality in these towns, which had increased in the four preceding weeks from 14·7 to 18·3 per 1000, further rose last week to 20·5. In London the rate was 20·5 per 1000, and corresponded with the mean rate in the thirty-two provincial towns. The lowest death-rates in these towns were 13·7 in Blackburn, 13·8 in Burnley, 14·0 in Halifax, and 14·3 in Swansea; the highest rates were 27·7 in Liverpool, 27·8 in Wolverhampton, 29·0 in Salford, and 29·1 in Preston. The 4410 deaths in these towns included 1127 which were referred to the principal zymotic diseases, against 575 and 796 in the two preceding weeks; of these,

Digitized by Google

902 resulted from diarrhœa, 74 from measles, 67 from whooping-cough, 43 from diphtheria, 25 from scarlet fever, and 16 from "fever" (principally enteric), No fatal case of any of these diseases was recorded last week in Halifax; in the other towns the lowest zymotic death-rates were recorded in Huddersfield, Gateshead, Oldham, and Blackburn, and the highest rates in Leicester, Liverpool, Preston, and Sheffield. The greatest mortality from measles occurred in Portsmouth and Plymouth, from scarlet fever in Norwich, from whooping-cough in Salford and Sunderland, and from diarrhœa in Wolverhampton, Birkenhead, Liverpool, Leicester, Sheffield, and Preston. The mortality from "fever" showed no marked excess in any of the large towns. The 43 deaths from diphtheria included 27 in London, 4 in Leeds, and 3 in West Ham. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and only one small-pox patient was under treatment in the Metropolitan Asylums Hospitals on Saturday last, August 13th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2293, against 2321 and 2326 at the end of the two preceding weeks; 201 new cases were admitted during the week, against 276, 232, and 224 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 173 and 174 in the two preceding weeks, declined again last week, to 171, and were slightly below the corrected average. The causes of 144, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bedford, Leeds, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Burnley, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·6 and 20·0 per 1000 in the two preceding weeks, declined again to 19·8 during the week ending August 13th, and was 0·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·7 in Dundee and 17·4 in Aberdeen to 20·8 in Glasgow and 26·4 in Greenock. The 598 deaths in these towns included 80 which were referred to diarrhœa, 17 to whooping-cough, 13 to measles, 12 to scarlet fever, 9 to diphtheria, and 5 to "fever." In all, 136 deaths resulted from these principal zymotic diseases, against 113 and 134 in the two preceding weeks. These 136 deaths were equal to an annual rate of 4·5 per 1000, which was 0·7 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had increased from 26 to 77 in the four preceding weeks, further rose to 80 last week, of which 46 occurred in Glasgow, 12 in Dundee, and 6 in Paisley. The 17 deaths from whooping-cough showed a decline of 13 from the number recorded in the preceding week and included 7 in Glasgow and 4 in Aberdeen. The fatal cases of measles, which had been 25 and 20 in the two preceding weeks, further declined to 13 last week, of which 4 occurred in Edinburgh and 4 in Dundee. The deaths from scarlet fever considerably exceeded the number recorded in any recent week and included 7 in Glasgow. The fatal cases of diphtheria, which had been 2 in each of the three preceding weeks, rose to 9 last week, of which 3 occurred in Glasgow, 3 in Greenock, and 2 in Dundee. Of the 5 deaths referred to "fever" 3 were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 79 in each of the two preceding weeks, declined to 71 last week, but exceeded by 13 the number in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these towns were not certified either by a registered medical practitioner or by a coroner.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·9 per 1000 in each of the two preceding weeks, increased to 25·5 during the week ending August 13th. During the past four weeks the rate of mortality in the city has averaged 24·0 per 1000, the rate during the same period being 17·8 in London and 19·3 in Edinburgh. The 171 deaths registered in Dublin during the week under notice showed an increase of 11 upon the number in the preceding week, and included 31 which were referred to the principal zymotic diseases, against 14 and 27 in the two preceding weeks; of these, 19 resulted from diarrhœa, 5 from whooping-cough, 3 from scarlet fever, 3 from "fever," 1 from diphtheria, and not one either from small-pox or measles. These 31 deaths were equal to an annual rate of 4·6 per 1000, the zymotic death-rate during the same period being 5·0 in London and 2·5 in Edinburgh. The fatal cases of diarrhœa, which had increased from 4 to 18 in the three preceding weeks, further rose to 19 last week. The deaths referred to different forms of "fever" which had been 3 and 5 in the two preceding weeks, declined again to 3 last week. The 3 deaths from scarlet fever exceeded the number recorded in any week since April last. The 171 deaths in Dublin last week included 42 of infants under one year of age, and 40 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons exceeded the number in any recent week. Eight inquest cases and 5 deaths from violence were registered; and 53, or nearly a third, of the deaths occurred in public institutions. The causes of 15, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff-Surgeons: A. G. Wildey to the *Hawke* and H. J. Hadden to the *Cruiser*. Surgeons: H. Hunt to the *Northampton*; John Grant to Malta Hospital; Beauchamp F. Parish to the *Ramillies;* George T. Bishop to the *Raven;* and Murray P. Jones to the *Vulcan*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Charles F. Pollock to be Colonel, vice W. A. Catherwood, promoted. The under-mentioned Majors to be Lieutenant-Colonels:—John Stevenson, William L. Lane, Patrick J. Dempsey, Kenneth S. Wallis, John W. H. Flanagan, Owen E. P. Lloyd, V.C., James G. MacNeece, Morgan D. O'Connell, Alexander S. W. Young, John J. Falvey, Horatio R. O. Cross (1st Life Guards), and Charles Seymour.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant John McMullen, M.B., 3rd Volunteer Battalion the King's (Liverpool Regiment) to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Royal Engineers: 1st West Riding of Yorkshire (Sheffield): Surgeon-Captain G. Robinson to be Surgeon-Major. *Rifle:* 4th Volunteer Battalion the Queen's (Royal West Surrey Regiment): Frederick Norman to be Surgeon-Lieutenant. 4th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Major W. S. Limrick to be Surgeon-Lieutenant-Colonel. 5th West Middlesex: Surgeon-Captain H. C. C. Shaw resigns his commission. 5th Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Robert Taylor Halliday to be Surgeon-Lieutenant. 1st Tower Hamlets: Surgeon-Lieutenant A. C. Tunstall to be Surgeon-Captain.

CADET BATTALION.

1st Cadet Battalion the Manchester Regiment: Acting Surgeon E. Proudlove resigns his commission.

THE RED CROSS SOCIETY AND THE ARMY MEDICAL AUTHORITIES IN CUBA.

A correspondent writes: Much friction has prevailed since the commencement of the American campaign in Cuba between the army medical authorities of the United States and the Red Cross Society. Chiefly through the agency of the lay press this bad feeling has now come to a climax and some of the medical journals have taken up the quarrel. From the first Dr. Sternberg, Surgeon-General of the United States Army, has set his face against the employment of women nurses at the front, giving as his reason that they are an encumbrance to an army mobilised for active operations and also pointing out that the Army Medical Department was well able to cope with the needs of the sick and wounded. However, of late there have come grave complaints from the front of the inadequacy of the army medical and nursing staff. Public indignation has been

Digitized by Google

greatly excited and has called forth replies both from Surgeon-General Sternberg and Lieutenant-Colonel Senn, chief of the operating staff with the army in the field, in which they defend the Army Medical Department from the attacks made upon it. Surgeon-General Sternberg draws attention to the fact that the deficiency in regular medical officers made it necessary to employ nearly 300 contract surgeons and that more are being employed every day. Most of these medical men from civil life are doing good service and many of them are thoroughly well-equipped physicians and surgeons with ample hospital experience, but it has been impossible to make a careful selection owing to the great pressure of business in the Surgeon-General's office and the urgency has been so great that it has not been practicable to have examining boards to verify their qualifications. General Shafter's army at Tampa, according to Surgeon-General Sternberg, was thoroughly well supplied with the necessary medicines, dressings, &c., for field service, but owing to insufficient transportation he left behind at Tampa his reserve medical supplies and ambulance corps. Surgeon-General Sternberg asks the medical profession in the United States to reserve its judgemnt until he has had the opportunity to receive full information regarding the efficiency of the medical service in the vicinity of Santiago. With reference to the overcrowded and dirty condition of the transports carrying sick and wounded it is understood that an inquiry has been ordered and steps will be taken to affix the blame to those responsible.

Correspondence.

"Audi alteram partem."

THE CLAIM OF MEMBERS AND FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND TO CHOOSE THE COLLEGE REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—As two of the Fellows and Members making the claim above mentioned, and as honorary secretaries of the subcommittee (F. and M.R.C.S. Eng.) of the Corporate and Medical Reform Association, Limited, which prepared the petition formulating the claim, and therefore intimately acquainted with the views of the petitioners and of the Committee, may we ask the favour of space for some explanations which your very powerful leading article in THE LANCET of July 23rd, 1898, on this claim appears to call for on our part? Your leading article in THE LANCET of April 2nd, 1898, p. 943, on the same subject frankly commended the terms of our influentially-signed petition, which the College Council has now rejected; and you say in that article: "In the end, however, the matter will possibly come before a court of law; for if the Council should come to the conclusion that they have acted rightly in appointing a person to be a member of the General Medical Council, then the petitioners and other Fellows and Members of the College who share their opinions will naturally endeavour to obtain an authoritative answer to the question 'to whom does the right of election belong?' On the other hand, should the Council of the College be of opinion that they have indeed usurped a function to which they have no legal right, it is probable that they would hardly feel justified in relinquishing the powers which they have already exercised for forty years except under the mandate of a court of law." We have been informed, we believe trustworthily, that the Council was equally divided on our petition; so that were Mr. Richardson Cross to act on the views submitted to him by Mr. George Jackson as a constituent and also by Mr. Horsley and other Fellows through us, though he is in no way pleged to do so, his single vote might turn the scale and secure a noble example of a new "self-denying" procedure. If this hope fails there remains that other hope which animates us, and which your suggestion so highly sanctions, of a "mandate of a court of law" to strengthen the hands of the conscientious "self-denying" members of the College Council. In that article you speak of "body corporate" as the "technical sense" of the word "body" used in the Medical Act. It is, we submit, the literal sense, and to show it to be technical some other sense should be adduced, which the very clear definitions of the College charters do not permit. In the more recent article (July 23rd) you give a list of the 20 "bodies," each of which should "choose" a member of the General Medical Council, and you state by whom the member is, in fact, at present sent to the Council in the case of each body. In only 3 instances out of the 20, it appears, is the member "chosen" by the corporation as a "body"—namely, by Oxford and Cambridge Universities and by the Apothecaries' Hall of Ireland. In all the other 17 instances the express terms of the Medical Act appear to be set aside. In the case of the 4 Scottish universities a two-line section of the Universities (Scotland) Act, 1889, amends, in effect, the Medical Act and vests the power of appointment in the several university courts. In all the other 13 instances the Medical Act is, it seems, violated and the franchise conferred by it unlawfully abrogated.

It is, therefore, very correctly you point out that Members and Fellows of the English College suffer whatever they suffer in this respect in common with the constituents of many other bodies. The insertion in the Universities (Scotland) Act, 1889, of the section we have mentioned affords fair inference that the Scottish universities were advised, and well advised as we maintain, that the Medical Acts vested the choice in the whole of each respective "body." Scottish graduates are already stirring in the matter, by means of their own select committee of the Corporate and Medical Reform Association; and Dr. James Myrtle of Harrogate has spoken to several Members of Parliament who fully admit the propriety of repealing that clause which furtively disfranchised 4 great constituencies—considerable sections of our profession. In the other 13 instances a favourable decision in the case of the Royal College of Surgeons of England would constitute a binding precedent, admitting to their rightful franchise all who are in fact constituents of the several "bodies." How greatly such a change would widen the present too narrow and oligarchic constituencies of the General Medical Council will at once be perceived. It would be contrary to every tradition of THE LANCET to question the expediency of such widening and unlike its practical common-sense views of medical politics to suggest that because this is not all the reform needed we should not endeavour to secure it, even though it may be within our reach. There is, we venture to submit, no evil which the profession at present suffers that is not to be traced to that narrow and selfish policy of the corporations which THE LANCET has consistently deprecated and censured. That selfish and narrow policy they could not have maintained for nearly half a century but for the control which their governing bodies obtained over the General Medical Council by the usurpation of this franchise to choose the members of that Council, and of that illegal control we believe we have the right, the power, and the opportunity to deprive them. A persual of the questions (Nos. 5 and 6) addressed in September last by certain electors—including Mr. George Jackson and Mr. Anderson, who are specially mentioned in your article of the 23rd ult.—to candidates at the recent election of a Direct Representative for England on the General Medical Council (which elicited favourable replies from Sir W. Foster, M.P., and from Mr. Victor Horsley, the rival candidates) will show that this claim was general and referred to the rights of all *de facto* constituents of all the bodies which should by law be represented on the Council.

These explanations, showing how far-reaching are our claims and how beneficial would be the effect of their establishment, may, we hope, more than satisfy any doubt on the score of expediency. Those who are actively asserting this claim are in full sympathy with the desire of the Members of the Royal College of Surgeons of England for a direct voice in the government of their own College, amongst them being Mr. Joseph Smith and Mr. W. G. Dickinson, the president and honorary secretary of the Society of Members of the College. But the College Council by its determined opposition has paralysed the Fellows; in the College the Members are absolutely helpless; and an agitation solely for the reform by Parliament of the College in this one particular would be so difficult in comparison with the measure under consideration that the advice to relinquish the easy assertion of a certain and possessory legal right in favour of the shadowy

Digitized by Google

expectations from such an agitation would—except that it is given by you, Sirs—appear like the effort of the lapwing to withdraw the dangerous intruder from her treasure.

The suggestion that our claim is in any sense technical may, besides consideration of the far-reaching changes its successful assertion would effect, best be met by the statement that it is a claim to reform—into compliance with the statute—what you well describe in clear and convincing terms as "the present method by which the representative of the College upon the General Medical Council is chosen by the Council of the College, and not by the corporation as a body," whereas the Medical Act, Section 7, specifically requires that the representative shall be chosen by the corporation as a "body" and *not* by the Council of the College.—We are, Sirs, your obedient servants,

TOM R. TAYLOR, M.D. Lond., F.R.C.S. Eng.
R. B. ANDERSON, F.R.C.S. Eng.

THE AMERICAN RED CROSS AND THE SPANIARDS.

To the Editors of THE LANCET.

SIRS,—Some time ago it was stated in the daily papers that the duty of rationing the Cuban belligerents allied to the Americans in their attack on Santiago was handed over to the Red Cross Society. This statement may not have been founded on fact, but if it were ever brought to the notice of the Spaniards that the American Red Cross Society was undertaking the important belligerent duties of a commissariat department it is not difficult to understand the "severe charge" "unreservedly" made against them by your special correspondent on board the hospital ship *Relief* to the effect that "they did not respect the Red Cross."

I am, Sirs, yours faithfully,

W. G. MACPHERSON, Major, R.A.M.C.

London, Aug. 11th, 1898.

THE PLAGUE AT HONG-KONG: OVERCROWDING IN THE CITY OF VICTORIA, HONG-KONG.

To the Editors of THE LANCET.

SIRS,—The following table is interesting as showing the surface overcrowding in a city where more than 1000 persons have this year died from bubonic plague:—

District.	Chinese houses.	Floors.	Chinese population.	Non-Chinese houses.	Non-Chinese population.	Acreage.	Total number of persons per acre.
1	503	811	7,720	31	428	531	15·3
2	955	2,353	21,120	—	1,108	267	83·2
3	18	33	4,210	355	1,869	158	38·5
4	776	2,341	23,230	128	1,834	45	556·9
5	980	2,686	21,720	21	351	23	959·6
6	805	2,308	16,680	3	398	23	742·5
	722	2,227	16,010	7	179	27	599·6
8	732	2,231	18,540	5	129	2	444·4
9	1,023	2,457	23,860	19	160	40	600·5
10	564	1,213	7,370	47	296	258	29·7
—	7,078	18,660	160,460	616	6752	1,414	—

Health District No. 3 contains not only the great majority of the European residences of the city but also the more important of the European shops and mercantile offices, to which are attached in many cases quarters for the office coolies and caretakers; in the other districts many of the European and other non-Chinese residents are compelled to occupy the upper floors of the better-built Chinese houses. A single medical officer of health deals with this crowded mass of humanity and the sanitary inspectors are very few in proportion to the population.

I am, Sirs, yours faithfully,

"ONLY ONE THOUSAND DEAD."

"HYPERPYREXIA IN MALARIAL FEVER."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 14th just arrived I have read with exceeding interest a case under the above heading recorded by Mr. Charles Lloyd Worrall. It is of particular interest to me, as scarcely two weeks ago I had under my care a case which to my mind is almost similar as regards the symptoms and physical signs, but different as to causation. As the particulars of the case might prove of interest not only to Mr. Worrall but to your readers, I will with your permission record it.

On June 15th at 7 P.M. a woman consulted me about her child, aged one year, which she had driven in a buggy from a neighbouring district sixteen miles distant. She stated that her child had been in excellent health from the day of birth up to 11 A.M. that morning, when shortly after returning from the usual morning walk with the black nurse it suddenly became convulsed. She at once immersed the child in a tepid bath for a short time, then wrapped it up in a warm blanket and put it to bed, when the convulsions ceased, but unconsciousness remained and a twitching of the right side of the body started; she then gave a dose of castor oil which proved effectual shortly afterwards. Seeing no improvement in the child's condition she consulted a neighbouring chemist, who prescribed potassii bromidi gr. 1 in a mixture to be given every three hours, but as this seemed to be ineffectual she deemed it advisable to consult me. On examination of the child I found it unconscious, the face was pallid, moist and clammy, there was continual twitching of the muscles of the right arm and leg, the eyelids were wide open, the eyeballs were oscillating, the irides were vacillating, and the temperature under the axilla was 105°F. I ordered the mother to remain at an hotel for the night, to at once give the child a tepid bath and put it to bed wrapped up in a warm, dry blanket, and prescribed a diaphoretic and bromide mixture to be given every hour. I again examined the child in half an hour's time to note the effect of the treatment and found that the twitchings of the muscles had ceased, the eyelids were now closed, and there was a profuse diaphoresis, but, to my surprise, I found the thermometer to register under the axilla 107·6°. Seeing that the temperature was rapidly rising and knowing that to trust to internal medication by antipyretics to reduce the temperature would not only be fruitless, but losing valuable time, I was about to proceed to apply more immediate measures, as the cold pack, when the child's breathing became very slow and laboured and it died in a few minutes; the temperature was 108·4° before death. Anyone comparing Mr. Worrall's recorded case with this one I think will agree to their similarity. Mr. Worrall attributes malarial fever as the cause of the hyperpyrexia in his case. Now in my case, although occurring in a malarious district also, still from the fact of there not being any malarial cases either at the time of the occurrence of this case or at least two months previously, or now one month since (and an isolated case of malarial fever of such severity occurring is very improbable), rather disproves that the plasmodium malariæ was the cause. More inclined am I to believe that the child whilst out walking with the black nurse was permitted to have its head exposed to the intense heat rays of the sun, thus causing a form of sunstroke.

I am, Sirs, yours faithfully,

ERNEST S. HAWTHORNE, L.R.C.P. & S. Irel.

Georgetown, N. Queensland, Australia, June 29th, 1898.

"PIPERIDINE AS A URIC ACID SOLVENT."

To the Editors of THE LANCET.

SIRS,—I am obliged to Dr. Tunnicliffe and Dr. Rosenheim for pointing out what was certainly an erroneous calculation in my paper contained in THE LANCET of June 11th as to the number of grains of a drug which it would be necessary to introduce at once into the circulation of an adult man of average weight in order to have 0·1 per cent. of the drug in the blood. I find that the number of grains should have been stated as 100 instead of 600. The calculation is based on the amount of blood being one-thirteenth of the body-weight. This alteration does not, however, affect any of the results or the conclusions deduced from the results arrived at in the paper

Digitized by Google

referred to. Dr. Tunnicliffe and Dr. Rosenheim state in their letter contained in THE LANCET of August 13th that the dose of piperidine tartrate should be 10 gr. instead of 15 gr. as originally stated by them. This would mean, on my revised calculation, that 0·01 per cent. of the drug would be introduced into the circulation if the whole of the ten grains were at once absorbed, and, as I previously pointed out, the only experiments described by the authors in their original paper as to the solvent effect exerted by piperidine on sodium biurate are with 0·1 per cent. solutions, or with 10 times as much as could be introduced into the circulation by the dosage they now recommend. In their letter of August 13th Dr. Tunnicliffe and Dr. Rosenheim, however, state that they experimented with 0·01 per cent. of the drug, though no mention of such experiments was made in their original paper, and that they found that such a percentage of piperidine tartrate increased the solvent power of the standard solution for sodium biurate one and a half times. This is the very evidence that was wanted, and, if such be the case, I shall welcome the drug as a most useful one for the removal of gouty deposits. With regard to the question of uric acid in bullock's serum I must still remain sceptical as to the proof of its presence until it has been identified by the murexide test.

I am, Sirs, yours faithfully,
ARTHUR P. LUFF, M.D. Lond.

Weymouth-street, W., August 17th, 1898.

"THE MUTUAL RELATIONSHIP AND RELATIVE VALUE OF EXPERIMENTAL RESEARCH AND CLINICAL EXPERIENCE IN LARYNGOLOGY, RHINOLOGY, AND OTOLOGY."

To the Editors of THE LANCET.

SIRS,—As the result of a series of inoculation experiments upon guinea-pigs with portions of naso-pharyngeal adenoid tissue removed by operation 16·4 per cent of the animals became tuberculous, and not 7 per cent., as stated by your reporter.—I am, Sirs, yours faithfully,

Manchester, August 15th, 1898. WILLIAM MILLIGAN.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Influence of Plague Inoculation on other Diseases.—Malaria and Plague.—The Health of Calcutta and Bombay.—Sad Accident to one of the English Lady Nurses.—The Need of a Pasteur Institute in India.—The Special Medical Officers.

IN a recent report upon inoculation among the Khoja community in Bombay M. Haffkine endeavours to show not only the protective value of inoculation against the plague, but that it influences also favourably the resistance to certain other diseases. The figures of mortality published certainly show a lower mortality from all diseases among the inoculated than among the uninoculated. This, however, does not prove his contention. Those who were inoculated may be well assumed to be the more enlightened and intelligent, they did not run away from the city like many others have done, they were not sick or weakly, and they did not consist of the very old or the very young. One would naturally look for a less mortality among the inoculated where inoculation is carried out with a naturally selected portion of a community. A difference of 89·7 per cent. in deaths from plague in favour of the inoculated part of the community is probably above the real value of the measure. However, inoculation has been shown to have considerable protective influence. A difference of 73·3 per cent. in deaths from what have been returned as "other causes" in favour of the same part of the community is too great to be trusted. That the occurrence of plague amongst a population has been associated with a diminished mortality from other causes has been recorded in many places and suggests either that the conditions which favour plague may in some unknown way be favourable to the general health of the population or that plague itself may in some unknown way affect the course of other diseases. It is an old observation that epidemics "clear the air," but the improvement or difference in mortality has never been anything approaching 73 per cent. I cannot help thinking that M. Haffkine has been trying to prove too much. It would probably have been more favourable to the cause of his prophylactic inoculation if he had limited his report to the confirmation of its plague-protecting influence.

There is one disease, at any rate, to which plague seems to have an antagonism. This is malaria. It is very suggestive that inoculation for plague should exert a favourable influence on the subject of malarial disease. Many persons who have periodically suffered from febrile attacks of malarial character have remained free from them after inoculation. The antagonism of one toxin to another, or to the development of certain forms of bacilli or other micro-organisms, is little known, but it is probably on these lines that some of the greatest achievements in experimental science have yet to be made known. This antagonism between plague and malaria may explain the practical escape of Calcutta and other places in the Lower Ganges from the present epidemic. I think it will be found that the most malarious districts have been free from plague or have suffered but slightly. It is certainly interesting to note the low general death-rate in Calcutta, Bombay, and Karachi while plague was existent in these cities and it is difficult to explain the sporadic character of the outbreak at Calcutta. Bombay at the present time has got an exceptionally low death-rate from fevers—equal to 50 per cent. below the normal. The deaths from plague exactly make up for the deficiency. The following figures show the gradual increase in the number of deaths from plague which is taking place and point to the probability of a third outbreak in Bombay. The general death-rate is about 33 per 1000.

Table showing the Number of Deaths from Plague.

For week ending May 31st ...	84	For week ending June 28th ...	53
,, ,, June 7th ...	44	,, ,, July 5th ...	38
,, ,, ,, 14th ...	26	,, ,, ,, 12th ...	53
,, ,, ,, 21st ...	15	,, ,, ,, 19th ...	63

An increase of plague has also occurred at Hubli, Bandra, and Thana, and in the Nizam's dominions.

Miss Harris, one of the lady nurses who were sent out by the Secretary of State for India on plague duty, has unfortunately been bitten by her own dog. The animal was ill and presented many suspicious symptoms, especially as it had been bitten by a stray dog a short time previously. More than ordinary caution was obviously indicated, but, unfortunately, in endeavouring to secure it Miss Harris was severely bitten on the hand. On this being reported she was advised to proceed by the next day's mail to Paris. The dog died from unmistakeable rabies the following day, but it must be ten days before Sister Harris can obtain the benefit of treatment at the Pasteur Institute. This is one more example of the necessity for the establishment of such an institute in India. Considering how prevalent rabies is, the difficulty of stamping it out in consequence of the wild animals, and the large numbers of half-starved pariah dogs everywhere continually scavenging about, the danger of hydrophobia is constantly present. The establishment of a Pasteur Institute has been talked about for five years and matters have proceeded as far as collecting over 77,000 rupees towards it, but what between the inadequacy of private support and procrastination on the part of the Government the project is still far from completion. The Supreme Government undertook a long time ago to provide the officer who would direct the treatment of the patients and the management of the laboratories. The question, however, is "still under consideration." It is not only for the treatment of hydrophobia that this scheme is required, there are many other ill-understood diseases which demand investigation. As natives of all classes have availed themselves of the benefits of inoculation against plague and cholera the serum treatment in general is hardly likely to receive further opposition.

Of the special medical officers sent out by the Secretary of State for India practically very few, except those of the last batch, remain. The authorities are now inquiring who will continue to serve with an increase of salary of 100 rupees a month. These appointments certainly give opportunities of seeing something of India, and the salary

Digitized by Google

more than covers ordinary expenditure. The work, however, from a professional point of view is very unsatisfactory. The present lull in the incidence of plague gives almost a holiday to the medical men and nurses, but there are ominous signs in many places of an early recrudescence.

July 23rd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Eye Hospital.

THE Birmingham and Midland Eye Hospital enjoys a wide reputation. It is the largest institution of the kind in the kingdom and its influence extends over a large area. At the annual meeting this year the report stated that the sum of £3778 19*s.* had been received in subscriptions, or upwards of £200 more than last year. The expenditure amounted to £6254 2*s.* 7*d.*, as against £5763 5*s.* in the previous year. The total number of patients treated during the year was 25,580, including 1140 in-patients. These figures show how extensive is the work done; 104 beds are nearly always occupied; 7019 cases were supplied with spectacles or artificial eyes during the past year; 384 cases of cataract were operated upon with success in all but 4; and 10 cases of extraction of steel or iron from the eye by the electro-magnet had been conducted to a successful issue. The committee regretted the resignation of Mr. Lloyd Owen, who for many years had been a member of the staff.

Overcrowding at the Gaol.

The report of the Visiting Committee of the city magistrates calls attention to the large increase in the number of prisoners at Winson Green Gaol and the urgent necessity for additional accommodation. A total increase in 1897 as compared with 1895 shows the number of 1167 more prisoners. The attention of the Home Office has been called to the matter by the chairman, but at present no definite response to the subject has been submitted. Serious difficulties must soon assert themselves if the present state of things is allowed to continue.

Training Institution for Nurses.

The death of the lady superintendent of this institution, Mrs. Diamond, has cast a gloom over those associated so long with her in this valuable work. For twenty-three years Mrs. Diamond had exercised an unusual amount of tact, courtesy, and success in the administration. With firmness and ability she ensured respect for the institution and gained the confidence of the public and of the nurses under her charge.

Ice-cream and Typhoid Fever.

Coseley, some few miles from Birmingham, is at present going through an unpleasant experience of an epidemic of typhoid fever. Close investigation has been made as to the causes to which this may be attributed. In at least 5 cases it has been traced to the consumption of ice-cream. This is sufficient to show that the indulgences of an early age are not free from risks and that the opportunity for the gratification of such tastes requires to be attended with precaution in the manufacture of this much sought-for dainty. Whether the authorities will be found equal to the occasion remains to be seen, though it is manifest that some intervention is strictly called for.

August 16th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Ptomaine Poisoning at Oldham.

A SERIOUS outbreak of ptomaine poisoning has occurred at Chadderton, Oldham. An inquest on one case, that of a boy aged thirteen years, was held by Dr. George Thomson, the coroner, at the Oldham Town Hall. It had been twice adjourned and was concluded on Tuesday, August 9th. On the day following Mr. Coroner Molesworth concluded an investigation at the Chadderton Town Hall as to the cause of death in three other cases, those of a man named Shaw, aged forty-five years, and two women, aged twenty-three and twenty-one years. Dr. Hodgson, who made a post-mortem examination in Shaw's case, deposed that he had died from diarrhœa, most probably set up by ptomaine poisoning. Dr. P. Bowes stated that he had attended 22 cases of illness, excluding the three deaths, in which the symptoms were all alike, and Police-sergeant Marsden deposed that he had made inquiries in 37 cases and in all but one veal pies from Mr. Baker's shop had been eaten; in the other case the patient had eaten a meat pie. At previous sittings and at the inquest on August 10th a number of witnesses said that they had eaten veal and pork pies purchased from Mr. Baker on Thursday, Friday, and Saturday, July 28th, 29th, and 30th. They spoke to the veal pies, which contained jelly, making them very ill, whilst the pork pies and some of the veal pies, which did not contain the jelly, were harmless. The butcher who supplied the confectioner, Mr. Baker, with the veal said that the calf was killed on July 26th at a licensed slaughter-house. It was ten or eleven weeks old and was healthy and the veal was sold at 8*d.* a pound. Similar evidence was given as to the sound condition of the pigs' feet, from which the jelly of the pies was made. Mr. Baker said that he made 160 veal pies on the Thursday and his wife said that she thought about 40 were sold that day. She and one of the children had one each that night and she believed another of her children had one on the Friday. She heard no complaints about the pies. Some details are given as to one of the victims, Elizabeth McConnell, who bought a pie on the Saturday night for supper. She had part of it and her father had a piece. Both became ill, but the latter recovered. The remains of the pie were thrown on the fire on Monday. In Mr. Molesworth's court the verdict in the three cases under investigation was that death had taken place from diarrhœa set up by the veal pies which had been overkept. "Under the special circumstances of the case they attributed no blame to anyone, but they wished to say that in future all meat pies during the hot weather should be baked and sold fresh daily"—an obviously sensible suggestion. George Coleman bought a pie on Saturday on his way to a cricket match, was very ill on the Sunday, and died on the Wednesday following. Like all the others, he had vomiting and diarrhœa. Dr. Thomson summed up the evidence and spoke at some length on ptomaine poisoning. He said that experience taught that these poisons "(1) develop almost invariably in cooked meat some hours after it is prepared; (2) pig meat is most prone to develop them; (3) that the jelly produced in cooking pig meat seems most to favour their development; (4) that one portion of a carcass may be infected while the rest remains sound; (5) that though infected the meat may be to sight, smell, taste, and touch apparently sound and good; and (6) that the infective germs may exist in the uncooked meat, may survive the cooking process and develop in the cooked meat." He put the following questions to the jury: Was death due to ptomaine? Was the veal supplied sound and good to all appearance when it left the hands of the butcher? Was it to all appearance sound when cut up and put into the pies? Were the pigs' feet used for making the jelly to all appearance sound and good when used? Did the ptomaine poison develop in the pies subsequently to the jellying process? To these questions the answer was, Yes. They also found that there was nothing in the appearance of the pies to indicate that any injurious change had taken place. They also found that the method of storing the pies after they were "jellied" was satisfactory, but they wished to add as a recommendation that the windows of all confectioners should be better ventilated by slides in the windows. It does not seem that any very fresh light has been thrown on the question of ptomaine poisoning, but the evidence certainly went to show that none of those suffered who ate the pies on the Thursday when they were quite fresh, while all those who bought them on the Saturday had attacks of vomiting and diarrhœa, many of them being of great severity and four being fatal. Dr. Bowes stated that "the malady was of so severe a type that the sufferers got into a state of complete exhaustion and that death in such a case would most likely be from collapse." No blame was attributed to the butcher or to the confectioner. There is still a good deal to be learned as to ptomaine poisoning.

Deaths from Diarrhœa.

As usual at this time of the year deaths from diarrhœa show a considerable increase. The week before last there

Digitized by Google

were 32, more than twice as many as in the preceding week, while the average for the previous six weeks was 7. The variations in temperature have been very great and rapid.

Hospital Sunday and Saturday Fund.

The results of this year's collections for the Hospital Sunday and Saturday Fund show a little falling back which we may hope is only temporary. In the Sunday Fund there was a slight increase, but in the Saturday Fund, which depends mainly on workpeople, there was a considerable falling off, "attributable to exceptional causes," presumably the unfortunate occurrence of strikes, leading to loss of wages and the transfer of trade and manufacture to other countries. The amount distributed to local medical charities this year is £7200 as compared with £7500 last year.

August 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

New Hospital, Aberdeenshire.

THERE has just been completed for the Alford District Committee of the Aberdeenshire County Council a district cottage hospital for infectious cases. The wards are well lighted and ventilated and will be heated by "Antislow" combustion grates. The water-supply and drainage works are very satisfactory. The hospital, which is capable of extension, will at present accommodate 16 patients.

Epidemics in Aberdeen.

Last week there were notified to the medical officer of health for Aberdeen 138 cases of whooping-cough, being 8 more than in the previous week, and 20 cases of scarlet fever, being 6 more than in the week preceding, and there were also reported 6 cases of erysipelas, 5 of measles (as against 14 in the week before), 2 of diphtheria, and 1 of typhoid fever. Nineteen cases were removed to the City Hospital, 1 to the Royal Infirmary, and 2 to the Sick Children's Hospital.

August 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Charitable Lotteries.

ONE of the favourite methods of collecting money for hospitals and medical charities in Ireland has been the establishment of a bazaar or *fête* at which lotteries have frequently proved a prominent and most lucrative feature. Many poor hospitals have benefited substantially by those mammoth bazaars for which Dublin has achieved a reputation. The lottery system has, however, in the opinion of many, been altogether overdone, for nowadays, scarcely a week passes during which books of lottery tickets for various charitable purposes are not freely circulated through the post. This method of "raising the wind" has just received a severe blow in the public action of his Excellency the Lord Lieutenant of Ireland. The Roman Catholic Archbishop of Dublin, Dr. Walshe, made a public protest some months ago in connexion with the gambling seductions of a bazaar organised by some of his co-religionists for what was recognised, however, as a most deserving institution. The effect was entirely satisfactory in reference to that particular project, but the protest was soon more or less forgotten, so that many, both Protestant and Roman Catholic, institutions in Dublin have since made use of the lottery system for obtaining money for medical charitable purposes. The recent public pronouncement of the Lord Lieutenant and the refusal of her Excellency the Countess Cadogan to patronise or to be present at a bazaar or *fête* in which a lottery for £100 proved a feature will certainly have a most salutary influence, the Countess being well known in Ireland as a most generous benefactor of charities of every description. The following is a brief account of what has just occurred. An advertisement appeared in the daily papers for some weeks of a bazaar and *fête* to be held at the Park, Kingstown, for the purpose of collecting funds for the construction of schools in that neighbourhood, the festivities to be patronised and opened by her Excellency the Countess Cadogan. Quite recently public placards notified that a lottery for £100 was to be held in connexion with the garden *fête*. His Excellency the Lord Lieutenant had his attention drawn to the lottery, and refused on the part of the Countess Cadogan to patronise the bazaar. His decision was conveyed in a letter, published in the morning papers, from his private secretary to Sir Percy Grace, one of the committee of the entertainment, in which he stated that her Excellency would not patronise or be present at the bazaar unless the lottery was withdrawn. The lottery project has now been abandoned and the Æstiva *fête* will be opened by the Countess Cadogan at Kingstown on August 17th.

The Public Health Congress and Exhibition in Dublin.

The Public Health Congress and Exhibition which opens on August 18th promises to prove the most interesting and important feature of the Dublin medical year. The programme of events has recently undergone revision, and it is now announced that the offices of the Royal Institute of Public Health and the Health Exhibition will be opened at 9 A.M. on the 18th inst. in the front hall of Trinity College for the issue of members' cards and cards of invitation to the Lord Mayor's ball and the various other entertainments, excursions, &c.

Queen's College, Belfast; the President's Report.

From the published report of the President of Queen's College, Belfast, for the past year I find that there were 223 medical, 135 arts, 28 law, and 17 engineering, students in attendance. Ten ladies attended the medical classes. During the last ten years the council has not been called upon to inflict a single penalty for breach of college law. A large number of honours have been gained by old students of the College during the year, and 953 volumes and publications were added to the library during the past 12 months. The natural history museum has been augmented in its accommodation by the erection of a new gallery, and "Two Friends," who desire that their names shall not be divulged, have given an unsolicited donation for the purpose of commencing the establishment of a museum of sanitary science. It has been decided to add a library to the Students' Union in which there are 255 members and which was worked so well financially that there is a balance of £42 3*s.* 3*d.* to credit. The Literary and Scientific Society will attain its jubilee next year. Both it and the Medical Students' Association continue to flourish. In conclusion, while the president thinks that in his judgment the College is as vigorous, its aims are as noble, and its work, within the limits assigned to it, is as successful as in the palmiest days of its history, he deplores the present unsettled condition of Irish university education. He feels, as one cognisant of the evils of the present situation and as one called to deal practically with it from day to day, that the existing position of affairs is well nigh intolerable, and he believes that the statesman who will rid us of it will be entitled to the everlasting gratitude of the whole community.

Londonderry Lunatic Asylum.

The overcrowded state of this asylum is causing a good deal of anxiety, as there are now in it 460 patients while it was only built to accommodate 344. In one corridor, which is only capable of holding and properly accommodating 36, 60 patients are sleeping. It was decided at a meeting of the board of the asylum held on August 11th, that the medical superintendent should again write to the Board of Control urging at the earliest possible date the completion of the temporary asylum.

Omagh Lunatic Asylum.

Mr. Alexander N. McKelvey has been appointed Assistant Medical Officer of the Omagh Lunatic Asylum.

Death of Mr. W. Sproule Love, M.R.C.S. Eng.

The announcement of the sudden death of Mr. Love on August 13th was heard with the most sincere regret in Omagh, where, for almost half a century, he was known and respected by every person in that town. A few years ago he had an attack of paralysis, in consequence of which he was partially rendered unfit for duty but he held so completely the confidence of the public that in times of serious illness his services were often demanded. It was while attending a patient in this way with Mr. Todd, J.P., of

Digitized by Google

Omagh, some distance from that place, that he was suddenly seized with symptoms of cardiac failure on August 12th and after being conveyed home he died on the next day at the age of seventy-two years.

The Campbell College.

This college, which was opened towards the end of 1894, was founded and endowed by a Belfast merchant, Mr. Henry James Campbell, who provided £200,000, his object being to furnish a superior liberal education. To carry out his purpose the original trustees purchased the demesne of Belmont, which is about 70 acres in extent, in the vicinity of Belfast, and erected under the guidance of their architect, Mr. W. H. Lynn, one of the best equipped scholastic edifices in the United Kingdom. The buildings are in the late Tudor style and contain a central hall surrounded by sixteen large class-rooms. A special feature is the science section, which contains a lecture theatre, two chemical laboratories, three physical and biological laboratories, instrument and balance room, detached workshops (wood and metal), and dark room for photography. The greatest care has been paid to the drainage, ventilation, and heating of the college, as well as to the construction of the infirmary and detached sanatorium. There is a cricket field (8 acres) and a football ground (10 acres). Until recently the government of the college was in the hands of the trustees, but it has been decided to form a new scheme for the Campbell College, and the governing body for the future will consist of the three trustees and twelve other members. The names of the new governors were published last week and amongst them are two members of the medical profession, Dr. Redfern and Professor Byers.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Cadaver Humanum: its Conservation.

ONCE and again THE LANCET has drawn attention to the ingenuity shown by Italian surgeons in immunising the dead subject from decomposition, and the theme has acquired fresh interest from its recent handling by Signor Luigi Ferrara. Throughout the peninsula, whether in its anatomical museums or in the family vaults of its *campi santi*, wonderful specimens of such successful immunisation are to be seen; but none of these can approach the perfection attained by Dr. Efisio Manini in a *métier* which may well be called national. For forty years that Neapolitan surgeon has striven to improve on the methods hitherto in practice, and his results, as known to the profession, throw all previous successes into the shade. "Without incisions"—so I am informed,—"without injections, simply with a series of baths, he has succeeded in preserving the human subject from all risk of decomposition whatever." His *modus operandi* consists of three stages. 1. Provisional desiccation, the so-called "conservazione allo stato coriaceo transitorio" (preservation applied to the corium in its transition period). Bodies so prepared and immersed in a liquid of his own devising may regain their primary freshness and be thereafter subjected to anatomical operations or demonstrations like the ordinary cadavera of the dissecting-room. 2. Petrifaction of the body so prepared—a process which, in Dr. Manini's hands, is so effective that the density as well as the consistency of marble is attained, insomuch that a few hours after the completion of this stage a key brought in sharp contact with the surface elicits a true metallic ring from the body. 3. The restoration to this desiccated and petrified subject of the freshness, the softness, the flexibility, and even the complexion of the natural state. As described to me the bodies so treated come from Dr. Manini's hands as if asleep, or in a condition of temporarily suspended animation. Well-known Italians dead within the last decade—like Benedetto Cairoli and Sanfelice—have been thus "stereotyped," so to say, for posterity and become to the anatomist, the anthropologist, and the medical jurist an object-lesson in the prosecution of their respective interests. In the last of these—that concerned with the investigation of capital offences—the gain to the resources of justice would be immense when contrasted with the means it has to fall back upon in Paris for instance, where the laborious process of keeping the dead body continually under waves of fresh air exhausts itself in a few days' time. Dr. Manini has been sustained in his life-long work by the sympathetic encouragement of surgeons like Nélaton and Billroth, and of anatomists like Richard Owen and Sappey. It is well known that had Napoleon III. kept his throne for a few months longer he would have placed the Neapolitan surgeon at the head of an anatomical museum specially devoted to the products of his *métier* and his methods, while it is an open secret that Dr. Guido Baccelli had decided to signalise his tenure of the portfolio of Public Instruction by making Dr. Manini director of a sanitary institution, when the fall of the Crispi Administration frustrated his decision. The veteran Neapolitan surgeon is now well stricken in years and Baccelli's successors in office have little time to lose if their country is to be spared the chagrin of again seeing one of her scientific *bene-meriti* receive from abroad the recognition denied to him at home.

The Pope's Health.

"Il Papa continua a stare benissimo" (the Pope continues in very good health)—such is the bulletin just received from the Vatican—confirmed, moreover, by his having the same morning celebrated mass in his private chapel and his having thereafter resumed his official audiences. The bulletin is all the more gratifying as the "sturbi viscerali" or intestinal catarrh from which he has been suffering constituted the "sharpest curve" his health has yet encountered in its comparatively even tenour. Ever since His Holiness ascended the throne in the February of 1878 he has been subject, though in a mild form, to such attacks, and last spring, when influenza was epidemic in the Eternal City and numbered victims even in the Sacred College, the dread lest the prevailing malady should overtake him, supervening on this "point of least resistance," redoubled the anxiety and the care of his body-physician. Besides this chronic or intercurrent malaise there is another drawback to his successful treatment—the change of air indicated from time to time is denied him, "prisoner" as he is "in a palace and a garden," albeit with doors locked on the inside. His twenty years' confinement, indeed, has told on him all the more severely since by birth a mountaineer and by tastes enamoured of rural life he misses his native "monti Lepini" and even the hill-country around Perugia where for many years he relieved the cares of his archbishopric by field sports. On the other hand, His Holiness is endowed with "the pulse of longevity" and the "æquus animus" of his favourite poet, and this, coupled with the "plain living and high thinking" which have been his characteristic through life, greatly reinforces the watchful skill of his medical adviser the Commendatore Dr. Lapponi, whose aim it seems to be, with the help of his able colleagues, to achieve for his august patient the distinction attained by Pio Nono alone in the long line of Pontiffs—that of falsifying the prediction whispered in the ear of each newly elected Pope: "Non videbis annos Petri" (thou shalt not see the years of Peter).

August 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Queen Victoria Homes.

THE first annual meeting of subscribers to the fund for the establishment of the Queen Victoria Homes for Consumptives was held in Sydney on June 27th, Lady Hampden presiding. It was stated in the report that although numerous and varied methods had been adopted by the committee to raise funds the total amount subscribed (£13,543) was disappointing. It was found that the support solicited for other institutions of a cognate character more or less militated against the efforts of the committee and especially an impression which prevailed that the claims of the Queen Victoria homes conflicted with those of the Thirlmere Home for Consumptives. The committee had arranged to take over the Thirlmere Home, Mr. Goodlet having generously offered the home rent free. It was to be hoped that the public would continue subscriptions, not only to maintain this admirable institution, but to increase its usefulness and to add to the capital fund of the committee until it attained

Digitized by Google

a sufficient magnitude to justify the committee in submitting a comprehensive proposal. Almost all the speakers expressed regret that the public had not responded more liberally and enthusiastically and urged that the necessity of providing for the phthisical patients must be brought home to the people's minds. The Hon. Dr. MacLaurin, in seconding the adoption of the report, gave some statistics as to the death-rate from phthisis. He said it was very satisfactory to know that during the last ten years a marked decrease had taken place in New South Wales in regard to the number of deaths from phthisis. Up to ten years ago the number had been increasing considerably. In 1885 there were 1095, when the population stood at 950,000, whereas last year, when the population stood at 1,320,000, the number of deaths was reduced to 964. For the years before 1885 phthisis had been increasing much more rapidly than the population, while now, although the population had increased 30 per cent., the number of deaths was very much less. The improvement which had taken place was even more marked with respect to the particular form of phthisis which mainly affected young children. In 1885 there were 271 deaths of young children from that disease in this country, whereas in 1897 the number of deaths was only 126. He thought the improvement which had taken place was attributable to the care taken to insure the purity of the milk-supply by the destruction of cows which were found to be suffering from tuberculosis.

The Sydney Hospital Saturday Fund Association and the Hospitals.

Reference was made last month to the complaint of the committee of the Hospital Saturday Fund Association that patients recommended by the officers of the association were not admitted to the hospitals without inquiry as to their financial position. The association authorities have now written to the hospital authorities demanding that the same privileges be extended to the subscribers to the fund as those extended to other corporate bodies. The board of directors of the Sydney Hospital decided to obtain legal opinion on the matter.

The Sydney Hospital and its Finances.

Some time ago a special committee was appointed to inquire into the financial working of the Sydney Hospital. The committee has now reported, the period over which its investigations extended being limited to the last three years. Most items of expenditure showed a considerable increase each year, but generally speaking this was accounted for by the increased number of patients treated and the increase in the prices of tradesmen's goods. The chief increase was in the out-patient department, where the number of patients had yearly increased and was now "inordinately large." The committee suggested: (*a*) that the number of out-patients treated each day should be limited except in urgent cases; (*b*) that after a patient has been under treatment one month he should be discharged and re-admitted if the medical officer deem it essential; and (*c*) as far as possible patients should be made to attend that hospital nearest to the place where they reside. The committee also suggested that the nurses' stipend should be reduced from £20 to £16 per annum in order to assimilate the training and pay of nurses at the Sydney Hospital with that at the Prince Alfred. The report was adopted with the exception of the proposal with regard to the nurses' pay. At a recent meeting of the board of directors a resolution by Dr. Freeman was carried "that no medical officer shall hold office after attaining the age of sixty years except as a consultant."

Austin Hospital, Melbourne.

The difficulties at the Austin Hospital, Melbourne, to which reference was made last month, have been satisfactorily settled. So much public feeling was expressed as to the retirement of Mr. Norcott that the committee had to give way and reinstate him. The honorary staff of the institution protested against the action of the committee, the patients presented an address, and the subscribers decided to hold a meeting and call the committee to account. The committee, however, forestalled the subscribers by reappointing Mr. Norcott before the meeting was held, at which its action in so doing was simply approved. It must be very gratifying to Mr. Norcott to find how highly his services have been appreciated and it is also satisfactory to find public sympathy accorded so freely to medical men in circumstances of the kind.

Medical Inspection of Vessels arriving at Port Phillip.

The Board of Public Health of Victoria recently decided to restrict the hours at which vessels would be cleared at Port Phillip Heads by the port health officers to from 6 A.M. to 6 P.M. in winter and to 7 P.M. in summer. The object of the change was to enable inspections to be made by daylight. A deputation from the representatives of the various shipping companies waited on the board to protest against the alteration and pointed out that great inconvenience would be caused both to passengers and shippers. It was observed that all the passenger ships were provided with electric light, which ought to be sufficient for medical inspection. The ship-owners also objected that the inspections are often unnecessary—in the case of vessels which have been already examined at other Australian ports and obtained "clean bills of health." The boats from China are overhauled by health officers six times in Australian waters before arriving at Port Phillip and in a period of sixteen days.

Tuberculin and Dairy Herds.

Mr. Cameron, veterinary inspector to the Board of Health, Victoria, has presented a report showing the result of his experiments with tuberculin as a test for tuberculosis in dairy cattle. If properly applied he believes it never fails. Characteristic experiments are made on the herds at the Leongatha labour colony. A number of cows reacted to the test and on being slaughtered were all found to have tuberculosis. Forty showed no reaction and fifteen months later were again injected and showed no reaction. Two were slaughtered and found to be free from tuberculosis. Mr. Cameron is satisfied that if the whole of the dairy herds in the colony were tested and the cattle affected condemned and slaughtered tuberculosis in cattle could be easily stamped out.

The Health of Tramway Employés.

The Commission recently appointed to inquire into certain grievances of the employés of the Melbourne Tramway Company has been taking medical evidence as to whether the gripmen and conductors suffer in health from their occupation or the hours of their service. The evidence was to the effect that they did not suffer more than other members of the community, and their health compared very favourably with that of other men working in the open-air—in fact, as a class they were healthier than men in other benefit societies and were not injured by the vibration of the cars, nor were they overworked.

Chronic Lead Poisoning in Queensland.

The Deputy Governor of Queensland has appointed the Hon. W. F. Taylor, M.D., D.P.H., M.L.C., W. W. Love, M.B.Edin., E. S. Jackson, M.B., C. J. Pound, F.R.M.S., and J. B. Henderson, Government Analyst, to be a board to inquire into and report upon the subject of chronic lead poisoning in Queensland.

Infectious Disease in Victoria.

The returns of cases of infectious disease for the fortnight ending June 25th show that typhoid fever and diphtheria were diminishing, but that scarlet fever is somewhat increasing in prevalence. The actual figures were: typhoid fever, 117 cases, 16 deaths; diphtheria, 72 cases, 11 deaths; and scarlet fever, 115 cases, no deaths.

Legal Actions by a Medical Man.

Dr. Gurdon, of Brighton, recently sued a patient for £17 6*s*. 6*d*. under somewhat unusual circumstances of interest to surgeons to friendly societies. Dr. Gurdon was medical officer to the local branch of the Ancient Order of Foresters and the defendant was transferred to his list from another lodge, as Dr. Gurdon supposed, of the same order. He found out, however, that defendant had been transferred from another order, the Protestant Alliance, and that the transfer was illegal. Dr. Gurdon returned the fees to the Lodge he had received on defendant's behalf and declined to attend him. He then charged defendant the ordinary fees for the attendance he had given him while on his Lodge list, amounting to £7 7*s*. The rest of the amount claimed was for previous attendance and for an accouchement for which he was engaged. The defendant declined to pay and Dr. Gurdon sued him. In his evidence Dr. Gurdon said defendant was well able to pay and not a suitable man to be in a Lodge. The bench struck out the fees charged while defendant was on the medical list, except for one visit given after Dr. Gurdon had given notice of his intentions, and also the accouchement fee, giving a verdict for £6 6*s*. and £1 6*s*. costs.

Obituary.

WILLIAM PEPPER, M.D. PENNSYLVANIA,

FORMERLY PROVOST OF THE UNIVERSITY OF PENNSYLVANIA AND PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE IN THE UNIVERSITY.

IN Professor William Pepper, whose death is announced as having taken place on July 28th at Pleasanton, in California, the world of science has lost a distinguished exponent of medicine and the United States a most public-spirited citizen.

William Pepper was born in August, 1843, so that at the time of his death he was not quite fifty-five years of age. His father, Dr. William Pepper, was a prominent physician and Professor of the Theory and Practice of Medicine in the University of Pennsylvania. Young Pepper imitated his father's example and graduated in medicine at the University of Pennsylvania at the age of twenty-one. He devoted himself at once to the study of clinical medicine and practical pathology and in 1868 was made Lecturer on Morbid Anatomy in the Medical School of the University. Two years later he became Lecturer on Clinical Medicine; in 1876 he was elected Professor of Clinical Medicine, and finally, in 1881, he became Professor of the Theory and Practice of Medicine, thus following in the footsteps of his father. In the same year he was elected Provost of the University, a post which he held until 1894. As a medical teacher he was enthusiastic and eloquent, as a diagnostician he was both careful and acute, while he left his mark on American medical education by his persistent advocacy of a longer medical curriculum for the student. When he was elected Provost the compulsory course for the student was only two years in duration. He at once raised it to three years and on his retirement from office gave practical and munificent effect to his views by a donation of 50,000 dollars, with a promise of 1000 dollars as an annual subscription for five years, towards an endowment fund to pay for greater teaching facilities for science in the University. In the same year the course was extended to four years.

Professor Pepper is known to the medical profession chiefly by his contributions to, and able editing of, the System of Practical Medicine by American Authors. This System, which was published in 1885, did for medical knowledge in America what Ziemssen's Cyclopædia had done ten years previously in Germany. It systematised and correlated the varying scientific opinions of persons all chosen to write because of their position and claims to know, and thus presented to the student a comprehensive account of disease in a series of authoritative monographs. Professor Pepper's contribution to the first volume dealt with Relapsing Fever and is an excellent example of how such monographs should be written. Utilising to the full his experience gained at the Philadelphia Hospital he refused to dogmatise concerning the etiology, preferring to help his readers by presenting them with a faithful clinical description and summarising for them all the best-known literature of the subject.

As a benefactor to his beloved city of Philadelphia Professor Pepper's actions were almost innumerable. He gave to the University the William Pepper Laboratory of Clinical Medicine in memory of his father; he inaugurated a system of commercial museums, to be connected with other museums in different parts of the country, wherein people might see specimens of the produce of all parts of the world; he secured immense donations for the Philadelphia Public Art Gallery and he founded the Free Library. We have not exhausted the list of Professor Pepper's public works, but we have said enough to show that in him Philadelphia is deploring one of the most generous as well as one of the most distinguished of her sons, while the medical world has to mourn the loss of an enlightened man of science, a wise teacher, and a liberal leader.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. H. Endres, *privat-docent* of Histology in the University of Halle.—Dr. Evert Julius Bonsdorff, formerly Professor of Anatomy and Physiology in the University of Helsingfors, at the age of eighty-eight years.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT EDINBURGH.

OUR report of the sixty-sixth annual meeting of the British Medical Association is now completed in the following account of the proceedings in certain of the sections. In finishing our report we wish to record our sense of the great courtesy that was extended at Edinburgh to our representatives by the editor of the *British Medical Journal*, the secretary of the Association, and the local secretaries and other officials responsible for the arrangements of the Edinburgh meeting.

THE SECTIONS.

MEDICINE.

FRIDAY, JULY 29TH.

Professor WRIGHT (Netley) opened a discussion on

The Serum Diagnosis and Therapeutics in Infective Diseases

The problem, he said, to be discussed was the nature of serum reactions and the relation of those reactions to the therapeutics of infectious disease. There were certain fundamental facts established by different observers in this domain. Pfeiffer was the first to observe that the serum of an immunised animal conveyed to the blood or serum of an animal into which it was inoculated the power of: (1) spherulating; (2) dissolving the micro-organisms; and (3) the power of neutralising the toxins which are set free by the dissolution of bacteria. Then there were Durham's and Gruber's observations that the blood of an immunised animal possessed the specific power of agglutinating and sedimenting the bacteria which were causally associated with the disease against which the animal (which supplied the serum) had been immunised. This was the fundamental principle of serum therapeutics, preventive and remedial. Lastly, Widal and Gruber and Grünbaum have shown that this power of agglutinating bacteria existed not only in the blood of animals which had recovered from and acquired immunity against a disease, but also in the blood of animals which were still the subjects of the disease. These observations suggested several very interesting problems. What was the nature of these substances upon which these properties of blood serum depended and how did they originate? Also what was the *rôle* these substances played in the production of immunity and recovery? The speaker then proceeded to consider these problems in the light which Ehrlich and others had cast on the nature and origin of antitoxins in the body. It was necessary first of all to understand the meaning of the terms "toxin" and "antitoxin" and how they were related. A morphological theory such as that of Metchnikoff, that toxins were poisons which were taken up into and destroyed by white corpuscles did not seem to help us. What was the use of erecting a morphological theory to explain what was obviously a chemical process? It might reasonably be asked what were the chemical processes which were associated with poisoning on the one hand and resistance to poisoning on the other. Ehrlich's chemical theory was far more reasonable—viz., that a poison was a substance which was capable of entering into chemical composition with, and interfering with, the functioning of protoplasm. Just as an aniline dye injected into the blood or tissues stained the nuclei and protoplasmic substance of cells by entering into combination with them, and therefore altering the chemical composition of those cells, so a toxin acted by entering into and altering the composition of protoplasmic cells. Further, Ehrlich had classified poisons by their chemical affinities into neurotropic toxins which had an affinity for nerve tissues, hæmotropic toxins which had an affinity for the blood, and so on. Then as to antitoxins, before Ehrlich published his theory no one was able to form any adequate idea as to what was the real nature of an antitoxin. It was true that Calmette had previously shown by experiments with venin and antivenin—the latter of which was destroyed by heat though the former was not—that an antitoxin

Digitized by Google

neutralised but did not destroy a toxin. Metchnikoff regarded an antitoxin as some property in the leucocytes which destroyed toxins (devoured them, so to speak), thus again starting a morphological theory to explain chemical facts. But Ehrlich's researches and observations had enabled us to define (and this was Ehrlich's theory reduced to its simplest terms) an antitoxin as a toxitropic substance which had a chemical affinity for a toxin and which joined itself chemically on to that toxin. Turning next to the origin of antitoxic substances it was not a substance specially manufactured for each occasion. Such an idea would endow the elaborative processes of the body with too great a power of "intellectual specialisation." It must be a normal constituent of the body of the animal which under special circumstances could be manufactured in greater quantity. Thus, as Ehrlich had put it, there were three steps in the process of elaborating an antitoxin when a poison or toxin was introduced into the body of an animal; first, there was loss or consumption of antitoxin, then replacement, then over-compensation. These were the three phases which took place in the manufacture of an antitoxin. In this way was the toxin rendered inert; firstly, by the chemical affinities of the antitoxin being satisfied and a neutral stable compound of antitoxin and toxin resulting, and then the animal was rendered immune by the over-formation of antitoxin. This had been proved by finding that if antitoxin be injected into an animal first and the toxin afterwards nothing resulted, no symptoms arose—they neutralised each other. These various steps had also been established beyond doubt by a series of experiments with ricin (a toxin found in castor oil seeds) and other poisons. The recollection of these facts was of the utmost practical importance. All these facts had had relation to toxins and antitoxins and their interaction one with the other. Turning to another set of experiments bearing on the relation of toxins to the different physiological systems, they had seen that tetanus toxin had a special affinity for the central nervous system. The first fact in time and importance in this connexion was that tetanus toxin had been shown to be partially neutralised by an emulsion of the central nervous system of a susceptible animal. If tetanus toxin were injected and at the same time an emulsion of this kind were also introduced the effects were considerably less severe. This showed that the central nervous system normally contained some substance which was antagonistic to a neurotropic toxin. On the other hand, snake venom and some other toxins were not rendered less toxic by the simultaneous administration of emulsions of brain and cord. This proved, extended, and confirmed the law that most toxins had their special affinities. Some toxins which had affinities for several of the physiological systems were known as polytropic substances. Another interesting fact in that domain was that one-fifteenth of the fatal dose of tetanus toxin, if applied directly to the nervous system, would be fatal. Professor Wright referred to the various attacks which had been made upon Ehrlich's theory and went on to consider whether that theory would account also for the production of anti-bacterial substances in the organism. The suggestion that the same theory which solves for us the problem of the production of antitoxins in the system was capable of solving for us also the problem of the production of anti-bacterial substances in the organism appeared at first sight to be eminently improbable. On closer examination, however, the matter wore a somewhat different aspect. For consideration showed that the neutralising effect which was obtained when antitoxins were incorporated into the body along with bacterial poisons was obtained in an equally marked manner in Pfeiffer's original experiment when anti-bacterial substances were incorporated along with bacterial poisons. They were almost certainly warranted in inferring from this fact that there was a close chemical analogy between antitoxins and anti-bacterial substances. In fact, they could infer from this experiment of Pfeiffer that antitoxins differed from the anti-bacterial substances only in this, that the antitoxins neutralised the biotoxins (i.e., the toxins which emanated from living bacteria), whereas the anti-bacterial substances neutralised the necrotoxins (i.e., the poisonous substances which emanated from the dead bodies of bacteria). It was obvious that the suggestion that Ehrlich's theory was capable of explaining the production of anti-bacterial substances in the body won support from the fact that there was a chemical analogy between these substances and antitoxins. Further analogies might readily be pointed out between the two classes of substances. But perhaps it would be better to come directly to the point and to ascertain whether the law which governed the production of antitoxins in the body was or was not also the same law as that which governs the production of anti-bacterial substances in the organism. They might begin by inquiring, as in the case of the antitoxins, whether anti-bacterial substances were already present in the normal organism. The answer to this question could not be doubtful for a minute. They had ample evidence that both bactericidal substances and agglutins were to be found in the normal blood and tissues. To take one example out of many, it was a matter of common knowledge that normal blood would agglutinate typhoid bacteria in all dilutions up to 1 in 4. They might next inquire whether the introduction of bacteria into the organism entailed upon the organism a loss of its normal bacteriotropic constituents. It would evidently be conformable to what occurred in the case of antitoxins if they were to find that such a loss of bacteriotropic substance actually occurred. It was certain, on *a priori* grounds, that such a loss of bacteriotropic substance did, as a matter of fact, supervene upon every bacterial inoculation. Further, it had been firmly established by experiment that when typhoid bacteria were grown in a culture medium which contained agglutins the agglutins disappeared from the culture medium *pari passu* with the growth of micro-organisms. Now, the conditions which obtained in such a culture medium were exactly reproduced when typhoid bacteria were cultivating themselves in the tissues of the invaded organism. Further, the conditions of the culture were reproduced in all their essential features when dead typhoid bacteria were inoculated hypodermically. They might thus infer from these experimental facts that both in case of typhoid infection and in case of anti-typhoid vaccination an appreciable quantity of bacteriotropic substance was withdrawn from the lymph and tissues. It followed from the foregoing: (1) that the conditions under which bacteriotropic substances were produced in the organisms were in all probability precisely similar to those under which antitoxins were produced; (2) they had seen in each case that a substance which was chemically identical with the immunising substance formed a normal constituent of the blood and tissues; and (3) they had also seen in each case that a substance which was chemically identical with the immunising substance was withdrawn from the tissues under the influence of an injection of bacterial substances. They need now only take a single step further and they would recognise that the production of the bacteriotropic substance in the organism was in all likelihood produced in the organism by just such a process of compensation and over-compensation for the loss, as takes place when toxitropic substances were produced in the body. Applying these facts to the therapeutics of infectious disease the issue of every infective disease depended upon two factors. It depended first upon the capacity of the bacteria for preserving their chemical integrity in the presence of the bacteriotropic substances which were normally present in the blood. It depended in the second place upon the capacity of the body-cells for preserving their chemical integrity in the presence of proto-plasmotropic bacterial toxins. The problem of therapeutics of infectious disease was the problem as to how we might intervene in these reactions in such a manner as to promote the disintegration of the bacterial protoplasm and prevent the disintegration of the cellular protoplasm. The disintegrating force which was brought to bear upon the bacterial protoplasm was represented by the affinities of the bacteriotropic substances for certain elements of that protoplasm. The primary object of our therapeutics must therefore be to give effect to those chemical affinities by increasing the quantity of available bacteriotropic substance. In like manner the disintegrating forces which were brought to bear upon the cellular protoplasm were represented by the chemical affinity of the protoplasmic tropic substances for the constituent elements of the cellular protoplasm. The secondary object of therapeutics must, therefore, be to diminish or nullify that disintegrating force by binding up the protoplasmic tropic substance which exerted that disintegrating force. With a view to doing this they must introduce antitoxic tropic substances into the blood. Here, however, an important point presented itself for consideration. This point had reference to the variety of antitoxin which was required. It had been customary, in consequence of the confusion of ideas which was traceable to the illogical state of the terminology, to assume that anti-bacterial substances could not possibly be of any avail against bacterial intoxications. Consideration would show that this was a capital error. It behoved them in every

Digitized by Google

case wherever they were dealing with an intoxication process to begin by inquiring into the nature of the bacterial poisons which were being introduced into the system. And if it appeared on inquiry that the bacterial poisons which were being absorbed into the system were, as apparently they were in the case of cholera, poisons which had formed originally part and parcel of the bacterial protoplasm, it was obvious that the appropriate antitoxin to apply would be not an antibiotoxin—i.e., it would not be a substance which was capable of neutralising the poisons which emanated from a living bacteria. The appropriate antitoxin would be an antinecrotoxin—i.e., a substance which possessed the power of neutralising the poisonous substances which were contained in the dead bacterial bodies. The truth of these conclusions appeared to Professor Wright to be confirmed in a striking manner by the fact that the anti-bacterial substances which were produced in the blood under the influence of Haffkine's anti-cholera inoculations appeared to exercise a very favourable influence upon the choleraic intoxication process.

Dr. GRÜNBAUM (Liverpool) wished to say a few words on the practical aspect of the question of serum diagnosis. The typhoid test was at first thought to be infallible, but now several modifications had taken place in the general opinion on this test. There were certainly two important factors to consider. The amount of dilution requisite was a point on which opinions differed considerably. He thought that 1 in 10 was not sufficient; as much as 1 in 20 was often required. Then as to the time required for the reaction, which must be limited, he thought that it ought not to be more than two hours. On the whole the serum test in typhoid fever should not, he thought, be regarded as a mere routine procedure which any office-boy could do; it required as much care, skill, and experience as any other scientific experiment.

Dr. H. E. DURHAM (London) thought that the opener of the discussion had placed too much reliance upon Ehrlich's theory. This theory was useful as a working hypothesis, but it seemed to him too precise and too definite to be carried out in its entirety. Its chief novelty lay in the introduction of the word "bacteriotropic" for "anti-bacterial." One must also bear in mind the limitations of the word "toxin," for, strange as it might seem, some toxins are not toxic.

Dr. MITCHELL BRUCE (London) wished to confine himself to the clinical aspect of the subject and based his remarks upon two cases in which antistreptococcic serum had been employed. The first was a case of septic endocarditis occurring in a child among a household in which measles prevailed. Three days before the child was first seen he had been operated upon for some affection of the throat. He shivered and in the course of the next day developed diphtheria, for which diphtheritic antitoxin had been employed, and from this the child recovered. But subsequently the child developed malignant endocarditis. The temperature chart and other particulars were given. Antistreptococcic serum was injected and the patient made a complete recovery. The second case was also a child who was admitted with fever, delirium, and drowsiness. The patient had frequent rigors, pains in the head and down the spine, restlessness, and delirium, with epistaxis from time to time. The most striking feature about this case was the intermissions of apparently perfect health, lasting for two or three days, which were followed by an attack of all the symptoms just mentioned, lasting several days. Among the symptoms also was a systolic murmur over the cardiac area. The temperature, of which a chart was shown, ran a typically pyæmic course. On the nineteenth day of the illness some antistreptococcic serum was injected. This was followed by the ordinary intermission, but two days later the temperature again went up and all the symptoms returned. In view of the success of the previous case and thinking that the serum used might have been fallacious, some was procured from another source and 10 c.c. were injected. Immediate and permanent recovery succeeded this. Dr. Bruce thought that the inferences to be drawn from these two cases were: (1) that we might confidently look for success with antistreptococcic serum in a considerable number of cases of septicæmia; (2) that the favourable effect, if any, was produced with remarkable rapidity; (3) that antistreptococcic serum might, as in both of these cases, succeed where other remedies had failed; and (4) it was most important to bear in mind that success might possibly attend one kind of serum after another kind had failed.

Dr. CLAUDE KER (Edinburgh) thought that Dr. Bruce's contribution was one of great value. In reference to the serum diagnosis reaction he was in the habit of using a dilution of 1 in 30 and giving a four hours' time limit. He had employed it on from 60 to 80 occasions and had only had 8 dubious results.

Sir JAMES GRANT (Ottawa) reminded the audience that so long ago as 1860 he had introduced the use of serum in cutaneous diseases with success and had published his investigations and results in the *Medical Times and Gazette* of 1863.

Professor WRIGHT, in reply, said he could not agree that the term "bacteriotropic" had the same significance and limitations as "anti-bacterial." The far-reaching character of Ehrlich's researches was difficult to over-estimate, and especially the establishment of the chemical nature of the changes, the fact that we have normally bacteriotropic substances in the blood, and finally and most important of all, the steps of loss, compensation, and over-compensation in the manufacture of antitoxin. The facts (1) that bacteriotropic substances were normally present in the blood and (2) that they were also in the blood of animals who were still the subjects of bacterial infection were some of the most important and certain data which had been established.

Dr. BEZLY THORNE (London) proposed the following motion, which was carried by acclamation: "That the Medical Section invite the Council to take such means as may seem most appropriate to press upon the legislature the urgent necessity of providing each sanitary district with a bacteriological laboratory which shall be available for the gratuitous examination of expectoration and other products, for the purpose of the early diagnosis of disease, and for the gratuitous supply of materials for the serum treatment of infectious disease."

Dr. ALEXANDER HAIG (London) gave a demonstration of the granules precipitated in the blood by chloride of ammonium (process of Barker-Smith) and gave an account of the process of estimating them by the microscope and some of their variations in health and disease. His contention was that under all conditions the number of granules vary with the quantity of uric acid passing in the urine, and a diagram was shown to illustrate this point. He had found the following to be the common relations of the granules and red cells—viz., in the domain of physiology the proportion was 1 to 10 in the morning and 1 to 20 in the evening, but more in children than in adults. In the domain of pathology he mentioned as examples, Bright's disease and chronic gout, in which the relation varied between 1 to 30 and 1 to 40. Any of these quantities could be reproduced by the action of drugs. A specimen of blood from Bright's disease and gout was shown in contrast with normal blood.

Dr. W. F. SOMERVILLE (Glasgow) read a paper on

The Importance of increasing the Respiratory Capacity in the Anæmias of Young Adults.

He said that anæmia in young adults was frequently seen by the practitioner. Doubtless the common feature of all such cases was deficiency in the red blood colouring matter, which must be due to many different causes and produce a variety of symptoms. He alluded to the causes of the conditions among the poorer classes, among which were insufficient and unwise feeding, bad ventilation, and overcrowding. Those more fortunately circumstanced were subject to over-pressure at school, which prevented their taking enough open-air exercise, and they often attended social functions at late hours. He spoke of the symptoms which led to such subjects seeking advice, instancing breathlessness, palpitation, neuralgias, disorders of menstruation, and muscular fatigue with slight cause. He recommended iron in combination with arsenic. The increase of hæmoglobin was mainly of value in improving the respiratory activities of the tissues; there must be abundant opportunities for the union of the hæmoglobin with the oxygen. It was the failure to realise this which explained the lack of benefit in some cases after prolonged administration of iron. Only by the complete restoration of blood function in such cases could a total cure be attained. Medicaments should be combined with the education of the respiratory mechanism. He went on to detail the methods of recognising whether an individual were using his respiratory muscles aright and adequately, and spoke of the great improvement in chest measurement, breathing capacity, appetite, and general tone established by complete and intelligent respiration and by adopting the methods which he advocated.

Dr. H. J. CAMPBELL (Bradford) read a paper on

Four Cases of Intracranial Disease.

The first case was that of a boy who had well-marked hemiplegia, but in whom the post-mortem examination only showed some distension of the lateral ventricle on the opposite side, together with some softening of the cerebral tissue; a few miliary tubercles were also present upon the basal vessels, the boy having died from acute general tuberculosis. The second case was regarded during life as one of a tumour of the pituitary body, but at the necropsy it was found that the symptoms arose from inflammatory deposit upon the dura mater in the sella turcica and on the optic groove and clinoid processes. The third case was one of hæmorrhage into the lateral, third, and fourth ventricles from rupture of vessels in the choroid plexus in a boy aged fifteen years, who had double congenital cystic kidneys. The last case was one of mitral stenosis with embolism of the posterior cerebral arteries in which the clot had blocked the openings of the arteries of the posterior perforated space without occluding the main trunks. From this there was partial recovery, but subsequently a second embolus occluded the basilar and caused death.

Dr. ALFRED P. HILLIER (South Africa) read a paper on

Chronic Dysentery.

The term "dysentery," he said, embraced a group of diseases affecting the large intestine, differing less in actual symptoms than in etiology and final pathological results. It occurred both sporadically and in epidemics; in the tropics and subtropics it ranked in malignancy and mortality with yellow fever, small-pox, and cholera as one of the four great epidemic diseases in the world. Dysentery was a very ubiquitous disease. Certain well-known predisposing causes so frequently produced it that one was compelled to believe that, if a micro-organism be indeed the cause, any condition setting up intestinal catarrh would provide a suitable soil for its growth and development, and that from the readiness of the onset of dysentery under this condition the micro-organism itself must be even more omnipresent than that of tuberculosis. Among the commonest predisposing causes were heat, exposure to wet and cold, impure water and food, starvation or irregular feeding. After dealing with the pathology, symptoms, and course of the disease Dr. Hillier referred to the line of treatment which his experience pointed to as most successful—the three chief remedies being opium, castor oil, and a milk diet used with discretion.

Papers were also read by Dr. T. R. FRASER (Edinburgh) on the Antitoxic Action of the Bile in relation to the Toxins of Diphtheria and Tetanus; by Dr. FAURE-MILLER (Paris) on the Use of Cold Baths in Typhoid Fever; and by Dr. A. STODART WALKER (Edinburgh) on Alcoholic Neurasthenia.

OPHTHALMOLOGY.

THURSDAY, JULY 28TH.

The discussion was opened on Mr. E. TREACHER COLLINS'S paper on

Cases in which Skiagraphy was effective for the Detection of Foreign Bodies,

an account of which was published in THE LANCET of July 30th.

Mr. NETTLESHIP (London) mentioned a case of a suspected foreign body in a child's eye which was on the point of being operated upon; skiagraphy gave rise to a negative result with regard to the presence of a foreign body. In this way the patient was saved from the inconvenience of an operation.

Dr. TATHAM THOMPSON (Cardiff) asked if the fluorescent screen was of any practical use in locating foreign bodies in the eye.

Mr. CARGILL (London) mentioned that he had had four cases which Mr. Mackenzie Davidson had skiagraphed and which had been operated upon with successful results.

Mr. MCHARDY (London) mentioned a case of injury to the eye which required the removal of the lens. A few days later irritation set in and Mr. Mackenzie Davidson located a foreign body behind the ciliary body; the electro-magnet was applied but failed to remove the piece of steel. The patient was advanced in years and the other eye being healthy the injured eye was removed; after removal the electro-magnet had to be applied several times before the foreign body was removed.

Dr. REEVE (Toronto) showed the apparatus which was used by Dr. Sweet in localising foreign bodies in the eye.

Mr. MACKENZIE DAVIDSON (London) replied that the use of the screen was only of service in the case of foreign bodies of considerable size, it being of no use in the case of small particles.

Dr. JAMES HINSHELWOOD (Glasgow) read a paper on

The Use of Holocaine.

A one per cent. solution when used gave rise to a burning sensation which in the course of from ten to twenty seconds passed into a state of anæsthesia which remained for one or two minutes. The drug when applied in this way did not affect the size of the pupil. It acted in half the time of cocaine and the effect was quite as marked and lasted longer. It also had no further effect on the eye. It did not affect the tension of the eyeball.

Dr. EDGAR BROWNE (Liverpool) stated that he had used the drug and had found it useful in cases of foreign bodies in the cornea.

The PRESIDENT (Dr. ARGYLL ROBERTSON) mentioned that he had been rather disappointed with its effects. He, however, explained that the solution might not have been well prepared.

Dr. HINSHELWOOD replied that the cases of failure were due to imperfectly prepared solutions; he stated that the solution should be freshly prepared every week, as it lost its effect after a time.

Dr. LESLIE BUCHANAN (Glasgow) read a paper on

Leuco-sarcoma of the Choroid.

He pointed out the rarity of this condition and described the structure of the tumour as being particularly vascular, consisting of a tubular arrangement of structure. The condition was even more malignant than glioma of the retina.

Dr. HILL GRIFFITH (Manchester) and Mr. NETTLESHIP made a few remarks and Dr. BUCHANAN replied.

Dr. C. H. USHER (Aberdeen) showed a case of Orbital Tumour with specimens.

Professor SNELLEN (Utrecht) gave an interesting historical review of

The Operations for the Treatment of Strabismus.

The first operation for strabismus was performed in 1839. He then described the various stages through which the operation had passed up to the present time. In the early operations the muscle was divided. These cases were followed by divergence and weakness of action. Then von Graefe cut the tendon and in this way controlled the amount of retraction by means of the attachment of the muscle to Ténon's capsule. Priestley Smith's operation by cutting out a portion of the tendon was next described. The condition of strabismus fixus (von Graefe) was alluded to; it was probably a congenital condition with adhesions between the eyeball and the orbit. These cases were difficult to operate upon.

Dr. WILLIAMS stated that the vast majority of cases of strabismus called for operation; in cases where there was very little refractive error correcting glasses had very little effect in removing the strabismus.

Dr. LITTLE (Manchester) mentioned that he frequently performed Snellen's horizontal incision with division of the tendon.

Mr. GEORGE BERRY (Edinburgh) described three cases of strabismus fixus in which he experienced great difficulty in finding the muscle. He also stated that in the advancement operation the stitches did not slip if they were introduced into the sclera; in that way they got a stronger pull upon the eye.

Professor SNELLEN replied by pointing out the great importance of correcting glasses in young children.

Mr. J. B. LAWFORD (London) read a paper on

The Operative Procedure for Cases of Incarcerated Iris.

He pointed out that the use of two knives in making the incision was a difficult operation, but prevented the loss of aqueous. The method he recommended was to pass a Graefe knife into the anterior chamber and straight across to the other side and draw the knife gently downwards and then remove; in this way two openings were made through which the iridectomies might be performed.

Dr. WILLIAMS and Mr. EDGAR BROWNE (Liverpool) made comments on the method.

Professor SNELLEN mentioned that he performed a small iridectomy to relieve the tension and that this was followed by a better cosmetic effect.

Digitized by Google

Mr. TREACHER COLLINS, Dr. GRAINGER, Mr. GEORGE BERRY, and Mr. LITTLE took part in the discussion, and Mr. LAWFORD replied.

Mr. R. WILLIAMS (Liverpool) described a case of

Paralysis of Accommodation after Influenza.

The patient had an attack of iritis and had a tuberculous tendency.

The PRESIDENT pointed out that the question of coincidence had to be carefully taken into consideration.

Mr. JULER (London) stated that it was his experience that paralysis of the third nerve was pretty common.

Dr. GEORGE MACKAY (Edinburgh) mentioned that he had used eserine ($\frac{1}{100}$ gr.) in the form of lamellæ with excellent results.

Mr. EDGAR BROWNE and Mr. CARGILL described similar cases.

Mr. WILLIAMS replied, stating that the point which he wished to bring out was the importance of the period of slow recovery in these cases as compared with the few weeks of post-diphtheritic cases.

Dr. TATHAM THOMPSON (Cardiff) described a case of

Cyst of the Hyaline Canal producing a Double Lens.

The patient complained of defective vision in the left eye both for near and distant vision objects, with occasional diplopia and latterly headache. She had been conscious of the defective vision for fifteen or twenty years. The vision of the right eye was $\frac{20}{20}$, that of the left eye being able to detect fingers at 12 ft. with undilated pupil. The external appearances were normal and the pupils were equal and active. On examination with the ophthalmoscope a peculiar irregularity was seen to exist in the refractive condition of the central area, which was very similar in appearance to that met with in "keratoconus." The pupil was dilated with atropine and on further examination a small transparent cyst was found to exist, lying close behind the lens and being like a drop of oil suspended in water. When the pupil was fully dilated and the eye was slightly rotated a sort of tail could be made out projecting backwards for a short distance.

Dr. A. HILL GRIFFITH and Mr. MARCUS GUNN made remarks.

Dr. ANGUS MCGILLIVRAY (Dundee) read a paper on the Hyaloid Canal and its Relation to Cyclitic Exudation.

Dr. J. W. EYRE (London) read a paper on a

Clinical and Bacteriological Study of Diplo-bacillary Conjunctivitis.

He said that both sexes and all ages were susceptible to this disease, although it was most common in middle-aged women. It was definitely contagious and was transmitted through the medium of the discharge. The incubation period averaged five days. The subjective symptoms were slight and consisted of stickiness or gumming together of the lids in the morning, slight photophobia, lacrymation, smarting of the eyes, and the presence of a small quantity of whitish discharge. The most marked feature of the disease was its chronicity, when untreated lasting for many months. The objective signs were fairly characteristic. At first limited to one eye, the disease soon became symmetrical. Small masses of greyish mucus-like discharge were noted adhering to the roots of the lashes and collecting in the neighbourhood of the caruncle. Slight injection of the bulbar conjunctiva and marked injection of the palpebral conjunctiva were present, together with an erythematous fringe along the free edge of the lower lid and some congestion of the caruncle.

Mr. ARNOLD LAWSON (London) read a paper on

The Bacteriology of the Normal Conjunctival Sac and its Bearing on the Use of Antiseptics.

Of 200 cases examined 41 tubes were sterile and 159 were fertile. A platinum wire loop was used in all the cases, it being thoroughly passed over the conjunctiva and then introduced into suitable media for cultivation.

Dr. J. EYRE and Dr. MCGILLIVRAY made remarks.

Dr. A. HILL GRIFFITH (Manchester) described a case of Successful Removal of an Orbital Cyst.

Dr. JOHN HERN (Darlington) read a paper on

The Operations which are now usually substituted for Enucleation of the Eyeball.

1. Evisceration. He transfixed the globe with a Graefe knife entered about two lines external to the corneal margin passed through the anterior chamber, and made a counter puncture exactly opposite to the point of entrance. The knife was now brought out beyond the corneal margin. Another incision was made with the scissors in the opposite half of the globe corresponding exactly with the incision made with a Graefe knife; thus the whole cornea was removed. Whatever remained of the iris and ciliary body was now removed by the curette, the operator being careful to retain as much of the vitreous as possible. The gaping wound in the sclera was next carefully stitched up. This left a good freely moveable stump on which in about six weeks an artificial eye could be fitted. The cosmetic effect was extremely good. 2. Mules's operation. In suitable cases, if done without delay (on the day of accident if possible), with strict antiseptic precautions, and if a glass ball be selected which fitted loosely with the emptied sclera, results were obtained which left nothing to be desired.

Dr. MCGILLIVRAY pointed out that in Mules's operation it was much easier to remove all the contents intact.

Dr. A. HILL GRIFFITH mentioned that he never had sympathetic trouble after evisceration.

Dr. LITTLE stated that in some cases the operation gave rise to a large amount of irritation.

The PRESIDENT pointed out that the glass ball sometimes came out and gave trouble. He suggested that the surface of the glass ball might be made rough and in that way prevent the slipping and secure more accurate apposition.

Dr. HERN replied.

Dr. G. V. MILLER (Stockton-on-Tees) related three cases of Myopia in which the subjective and objective methods of testing refraction differed.

FRIDAY, JULY 29TH.

Mr. HENRY JULER (London) read a paper on

(1) *A Case of Gumma of the Ciliary Body with Recovery of Vision.*

He stated that intraocular syphilomata were rare lesions of the eye. When a gumma started within the eyeball it did so either in the iris, ciliary body, or the choroid. The case was that of a single man, aged twenty-five years, who was suffering from severe plastic iritis in both eyes. He had contracted a chancre on the penis, which was followed a month later by secondary manifestations of syphilis. He developed iritis in the right eye and a few days later the left iris became inflamed. There was much effusion of lymph and several orange-coloured deposits in both irides occurred. The right pupil was small and irregular with broad synechiæ; the left pupil was somewhat larger and also irregular. The pupillary area contained lymph. The tension of both eyes was normal. The outer part of the anterior chamber was shallow. The tension was, however, not raised. Vision could only detect fingers. There was intermittent pyrexia. A painless effusion into the knee-joint along with double orchitis and a gumma on the lower end of the right fibula occurred and somewhat relieved the eye condition. The subject of ciliary gummata had recently been brought to notice by Vernon Cargill. The lesion was a very destructive one and vision, if any be retained, was very bad indeed. The case was therefore unique in this respect and exemplified the possibility of almost complete restoration of sight. Mercurial treatment was given until salivation and stomatitis took place. Then potassium iodide was given and atropine throughout. Bull stated that choroidal gumma rarely or never occurred.

(2) *Case of Interstitial Keratitis with Acquired Syphilis.*

This case was that of a married woman who developed a sore on the genitals six weeks after marriage. The eyes were painful and the corneæ were cloudy. She could count fingers with difficulty. The pain increased and photophobia, anæmia, and despondency were also present. Iodide of ammonia was given. Then mercurial treatment was given in the form of inunctions. Blood began to appear in the corneal tissue. The punctate opacities commenced to disappear. The vision improved until it became $\frac{6}{9}$. Bull classifies four groups: (1) diffuse parenchymatous or interstitial keratitis; (2) true keratitis punctata of Mauthner; (3) keratitis punctata with general cloudiness of the cornea; and (4) gummatous keratitis.

Dr. HINSHELWOOD mentioned a similar case which had been treated as one of lupus of the nose. The patient was put upon mercurial treatment and she improved rapidly.

Mr. LAWFORD, Mr. JULER, and the PRESIDENT took part in the discussion.

Mr. FALLOWS (London) read a paper on (1) a case of Polypoid Growth from a Meibomian Gland, and (2) the Use of Fluorescin in the Form of Tabloids in the Diagnosis of Corneal Abrasions.

Mr. H. E. JONES (Liverpool) read a paper on Irrigation for the Nasal Duct.

Mr. JULER and Dr. GEORGE MACKAY remarked on the instrument.

Mr. JONES replied that he used boric solution. He did not use corrosive sublimate owing to its effect upon the canaliculus.

Mr. CHARLES WRAY (London) read a paper on Extraction of Transparent Lens in High Myopia. Up to August last over 2000 patients with myopia over 10 D. had been submitted to operation. The immediate results were good but the ultimate results were bad.

Mr. JOHN GRIFFITHS related particulars of a case of Acute Exophthalmic Goitre.

Dr. GEORGE MACKAY described a case upon which he had operated.

Dr. A. HILL GRIFFITH mentioned a similar case in which he had used thymus extract.

Mr. MARCUS GUNN stated that electricity had been found useful.

Dr. A. BRONNER read a paper on Crystals of Cocaine in preference to Solution.

LARYNGOLOGY AND OTOLOGY.

FRIDAY, JULY 29TH.

Dr. JOBSON HORNE (London) read a paper upon

The Pathogenesis and Earlier Clinical Evidence of Laryngeal Tuberculosis.

He said that it would not be possible for him to do more than touch upon the threshold of the disease and endeavour to demonstrate what appeared to him to be the portal of infection, the beginning and progress of tuberculous destruction, the origin and formation of the giant cell, and briefly indicate the clinical counterparts of the early pathological changes which he had learnt to regard as the earliest signs and symptoms, not only of laryngeal tuberculosis, but also of pulmonary tuberculosis. A lantern demonstration was given of photographs of microscopic sections on which the conclusions were based and some of the more important sections were shown under microscopes. The pathogenesis of the disease had been studied in larynges which post mortem presented to the naked eye none of the usual signs of laryngeal tuberculosis, but which had been removed from bodies of persons who had died undoubtedly from tuberculosis. In the examination of these larynges films were first prepared from the contents of the ventricles and stained for tubercle bacilli and the larynx was afterwards examined microscopically throughout. Dr. Horne dwelt upon the importance of the ventricle as a harbour for tubercle bacilli. The earliest changes noted in the lymphatics were a proliferation of the parenchyma of the acini and efferent ducts and the formation of masses of small round cells distending and choking the ducts and obliterating the glands, the adjacent and superficial structures remaining intact. These changes had been noted in the lymphatics situated in the walls of the ventricles when a careful microscopic examination of the entire larynx had failed to reveal changes in the lymphatics in other parts. The nature of this cell proliferation was next considered. Was it to be regarded as nothing more than an outcome of a traumatism or of some simple catarrhal process perhaps peculiar to tuberculous subjects? or was it to be attributed to one specific cause—namely, the presence of the tubercle bacillus? Dr. Horne said that although he was not prepared altogether to accept or reject the theory that these lymphoid masses were due to a simple catarrhal process, he was now able to demonstrate the tubercle bacilli in the midst of some of them and was of the opinion that once having gained an entry into the lymphatic ducts they acted as an irritant and caused a cell proliferation. The *fons et origo* of the giant cell in tuberculosis next came under consideration and by a series of lantern photographs of microscopic specimens its development from the wall of a lymph space was demonstrated. The series showed first the tubercle bacilli lying amongst the endothelial cells forming the wall of the lymph space; secondly, the division and fusion of the adjacent and divided cells; and thirdly, the separation off of this plasmodial mass as a giant cell. Reference was made to the researches on lepra laryngis by Dr. Paul Bergengrün of Riga, in which he had shown that the so-called "globi" were bacillary thrombi lying in dilated lymphatics and that the lepra giant cell developed from the lymphatic endothelium. If, then, as would appear to be the case from the foregoing, the tuberculous process commenced in the lymphatics it would be natural to suppose that those parts which were rich in lymphatics would be the more common sites for infiltration and ulceration, while such parts as were without glands would escape ulceration except by continuity. This was clinically verified. The inter-arytenoid region, the posterior third of the cord, the ventricular band, and the epiglottis, especially the petiolus, were the parts more richly endowed with glands and these were the parts more commonly ulcerated in laryngeal tuberculosis. The cord, the functionally more important part of the cord,—namely, that part lying between the two small cartilaginous bodies—being free from glands escaped ulceration excepting superficial erosion and by continuity. A proliferation of the subepithelial blood-vessels was described as taking place side by side with this cell proliferation. With regard to the muscles, changes were described as occurring at an early stage in the fibres and as being clinically brought into evidence by an early functional failure which was mainly myopathic. The earlier clinical evidence of laryngeal tuberculosis, the clinical counterparts of these early pathological changes, were next described. Whilst clinically investigating these it was necessary, inasmuch as only slight departures from the normal were being looked for, to retain a control mental image of a normal larynx. This was done by constantly examining a large number—some hundreds in all were examined—of larynges in healthy subjects or at least presumably free from tuberculosis. And it was whilst in search of normal larynges that some important aids to the present research were stumbled upon. The larynx had been examined in 359 consecutive cases of pulmonary tuberculosis or cases in which there were reasons for suspecting pulmonary disease. The points to which attention was mainly directed were the following: (1) disturbances of sensation, hypæsthesia, hyperæsthesia, paræsthesia; (2) colour changes, anæmia, hyperæmia; (3) functional disturbances; (4) impaired movements of vocal cords apart from paralysis; and (5) changes in the contour of the larynx due to slight œdema. Inasmuch as disturbances of sensation were subjective too much significance could readily be attached to them if taken alone as a clue to pulmonary tuberculosis, but in regarding them only as evidence of "hysteria" one was apt to miss important clues to pulmonary tuberculosis. Hypæsthesia was not infrequently associated with anæmia of the soft palate, and it might be stated that unless the subject was wilfully hostile to laryngoscopy the more pallid the soft palate the greater the tolerance to laryngoscopy. And when in the course of the pulmonary condition the anæmia passed off the tolerance often went with it. Anæmia of the laryngeal mucosa was noted as present in varying degrees in 157 out of 359 cases. At times it was universal; when patchy it was confined to points where the mucosa was more easily exposed to tension, occasioned by a slight œdema in association with the proliferation of subepithelial vessels. It was as frequently met with in men as in women. Hyperæmia was noted in 117 out of 359 cases and rather more frequently in males. This hyperæmia must be regarded as a feature distinct from and not amounting to acute laryngitis. Acute laryngitis did not occur so frequently as one might previously have anticipated. The hyperæmia was often transient, within a few days giving way to pallor; but at times it was most persistent. These phenomena were also attributed to the proliferation of subepithelial vessels. Disturbances in the vocal function were most frequently met with, often transient, not amounting to more than a weakness of voice or loss of tone. The production of voice called for a greater effort, there was a forgetfulness of office, a sluggishness of one or both cords to act, so that there was phonatory waste before voice was produced, and in connexion with this required effort might be mentioned that in early tuberculosis when the speaking voice was weak the singing voice was quite clear. Then the singing voice might suddenly go; this caused the patient to seek advice, and the possibility of commencing tuberculosis should not be forgotten. Transient dysphonia was more commonly met with amongst women, and especially young married women, during pregnancy. Not infrequently in cases of so-called "hysterical aphonia" thoracic signs of pulmonary tuberculosis had been subsequently made out, and it was as well to bear in mind the possibility of diagnosing "hysterical aphonia"

Digitized by Google

in the presence of pulmonary tuberculosis. Impaired movement of the vocal cords apart from paralysis was described and considered to be myopathic in origin and due to the changes noted in the muscle fibres. With regard to transient œdema of the laryngeal mucosa, the contour in a large number of larynges in early pulmonary tuberculosis when compared with that existing in a normal larynx was found to be partially lost, more particularly in the inter-arytenoid and arytenoid regions along the ventricular bands, and at the base of the epiglottis. A fine crenating or fringing occurs upon the folds of mucous membrane in the inter-arytenoid space, not sufficient to be called an excrescence, but met with sufficiently often in pulmonary tuberculosis as to be deserving of attention. An early but transient loss of symmetry in the outline of the arytenoid eminences occurred. The ventricles become less patent and this loss of patency was commonly associated with some œdema of the inner wall of the ventricular band, which was ascertained clinically in endeavouring to pass a curved platinum loop into the ventricle in search of tubercle bacilli. A slight œdema of this part of the ventricular band, together with an enfeebled action of the compressor sacculi laryngis, must effectually retain sputum laden with tubercle bacilli within the ventricle when once it had been lodged there in the act of coughing. Moreover, it was pointed out that the choking by a cell proliferation of the ducts of the muciparous glands opening into the ventricle, the closure of the ventricle by the œdema secondary to the proliferation of vessels, and the failure of the compressor sacculi laryngis through changes in the muscle fibres to discharge its contents, all combine to deprive the cords of the mucus necessary for their lubrication. The cords lose that semi-translucent mother-o'-pearl sheen and present an opaque pallor more approaching a dead ivory-white. With insufficient lubrication superficial erosions occurred; this did not amount to ulceration as met with elsewhere in the larynx inasmuch as the essential element was absent—namely, the lymphatics.

DERMATOLOGY.

THURSDAY, JULY 28TH.

Professor BOECK (Christiania) opened a discussion on the

Nature and Treatment of Lupus Erythematosus.

He first referred to the various forms in which the disease might be met with and then emphatically stated his belief that lupus erythematosus was a tuberculous disease. Out of a large number of cases which he had collected 28 had presented some internal tuberculous manifestations, 8 had developed tuberculous glands in association with the disease, and 23 had presented enlarged glands in some part of the body. Only one-third of the total number of cases had not presented any tuberculous manifestation. After describing the various diseases for which lupus erythematosus might be mistaken, he summed up the histological evidences which he regarded as supporting the view that the disease was of tuberculous origin, viz.—(1) the presence of giant cells in the lesion; (2) the presence of small migratory cell infiltration; and (3) the destruction of the intercellular tissue. He also thought that the presence of peripheral nerve disturbance favoured this view.

Dr. UNNA (Hamburg) took an entirely opposite view. He thought that the disease was wholly unconnected with tubercle, though clinically the condition had some superficial resemblance to lupus vulgaris, which was universally admitted to be a true tuberculous process. He emphasised the value of thorough histological investigation of every case and adduced the histological features as against the tuberculous view. Not only had there never been found any evidences of tubercle bacilli in the lesion, but the characters of the process did not accord with those of tuberculous lesions of the skin. The overgrowth downwards of the horny processes of the epidermis should not, he said, be confused with comedones. There was a peculiar moisture which was quite characteristic of lupus erythematosus, accompanied by a cellular overgrowth which was not found in dry scaly conditions, and it was this which led him to prefer desiccating remedies. As regards internal treatment he favoured alkalies, carbonate of ammonia, ichthyol, and salicylates, all of which were useful but unable to cure without external remedies. On the other hand, external remedies could often cure without internal remedies. He exhibited a valuable table classifying external remedies in the treatment of lupus erythematosus. Group 1 consisted of desiccating remedies, such as powder of oxide of zinc, powder of calamine, powder of bismuth, &c., or sulphur zinc paste or washes consisting of lead lotion, lime water, &c. These soothing remedies were very valuable but were very tardy in their action. Group 2 consisted of compressing remedies for the removal of the œdema of the skin—collodion with ichthyol or salicylic acid, zinc, gelatin, compressing bandages, masks, &c. Group 3 consisted of anti-hyperæmic remedies such as plaster mulls or pastes of chrysarobin, ichthyolsulfon, and mercury. Among these he had tried pyraloxin, which he believed to be a very dangerous remedy. The micro-cautery (with tiny points) might be classed in this group, and he recommended a platino-iridium point in preference to a point of platinum. Group 4 consisted of necrotising remedies which were of two degrees: (*a*) peeling remedies such as salicylic soap, plaster mull, zinc, resorcin paste, &c., and (*b*) ulcerative remedies such as pyrogalol in strong doses, sublimate, and the Pacquelin cautery. Group 5 were inflammatory remedies. Of all these the anti-hyperæmic remedies were, he believed, best for cure, the compressing remedies coming next in order, and the desiccating or soothing group being also valuable.

Dr. MORGAN DOCKRELL (London) expressed the opinion that there was no evidence of lupus erythematosus being tuberculous, and urged that the name was very misleading. The term "lupus," he thought, should be given up and a term like "atrophic erythema" or "ul-erythema" used in its place. It was true that lupus erythematosus occurred sometimes on a tuberculous soil and led to a compound condition, but he was persuaded of its non-tuberculous origin. In reference to the treatment of the condition he quite supported Dr. Unna's remarks on the value of the soothing treatment, and found that he could always stamp out the disease without the use of irritants.

Dr. EDDOWES (London) narrated a case of lupus erythematosus which he thought might have some tuberculous origin on account of the circumstances under which it arose. He had taken pieces of skin from the patient and inoculated guinea-pigs in the laboratory at St. Bartholomew's Hospital, but with negative results. As regards the treatment he recommended lead and calamine lotion as a daily application, and generally applied a solution of ethylate of sodium to obstinate cases. Scarification was sometimes useful and so was acid nitrate of mercury, though this was severe. These remedies were the best with which he was acquainted. Quinine, as recommended by Dr. Payne, was often very beneficial but apparently did no permanent good.

Dr. MAAR (Copenhagen) mentioned the results of the treatment suggested by Professor Finsen of Copenhagen, who had employed in the treatment of lupus vulgaris and lupus erythematosus the chemical rays of electric light or sunlight by the exclusion of heat rays. In the few cases in which that treatment had been tried a successful result had been obtained by persevering with it for a long time.

Dr. LESLIE ROBERTS (Liverpool), Dr. STOPFORD TAYLOR (Liverpool), and others took part in the discussion.

Mr. MALCOLM MORRIS (London) then opened a discussion on

What do we Understand by Eczema?

The nature of eczema, he said, was a subject which had engaged the attention of dermatologists ever since the time of Willan; but although a great deal was known about eczema they were not agreed as to what it really was. Was it a special process following certain laws in its evolution and manifesting itself by definite characters, or was it a clinical expression denoting results of several forms of morbid action? His own conception of eczema was expressed in the following definition, which he had given five years ago: "A catarrhal inflammation of the skin originating without visible external irritation and characterised in some stages of its evolution by serous exudation." The terms of this definition excluded all forms of artificial dermatitis—i.e., inflammation of the skin produced by chemical or mechanical irritants. Lesions due to such causes might be exactly like those of genuine eczema, but there was the fundamental difference that they appeared in response to a visible cause and began to disappear when the cause ceased to operate. On the other hand, true eczema arose without obvious cause; the skin might be healthy or there might be some pre-existing abnormal condition. The older dermatologists, following Bateman, regarded eczema as a vesicular eruption caused by an external irritation, "by the rays of the sun or the irritation of various substances applied to the skin, or by mercury taken internally, though it was found

Digitized by Google

associated with gastro-intestinal inflammation without any mercurial preparation having been taken." Bazin, whose influence long dominated the French school, saw in eczema an expression of various constitutional conditions such as scrofula, arthritism, or herpetism. In that way various forms of eczema were easily accounted for by their dependence on some real or hypothetical dyscrasia. This constitutional theory gave place in turn to Hebra's doctrine that eczema was nothing more than a superficial inflammation of the skin due to some external cause—i.e., the effect of a local irritation. At the present time, under the influence of Unna, many dermatologists are coming to look upon eczema as a parasitic disease; and another view which had many supporters in the present day was that it had its origin in some disordered action of the nervous system. There were facts in favour of each of these agencies, and Mr. Morris himself was inclined to the view that in many, if not all, cases they were combined — a view which seemed to explain the facts better than any other which had hitherto been suggested. In considering the parasitic view he referred to the researches of Unna, who had found parasites which he regarded as specific both in vesicular and in seborrhœic eczema, namely, cocci, which were often found in clusters resembling mulberries, and therefore he proposed the name morococci for these micro-organisms. They could be found in the cellular protoplasm of the elements of the vesicle. In seborrhœic eczema Unna had found morococci, "flaschen" bacilli and other bacilli of indeterminate character in the crusts and scales. Unna had cultivated the morococcus and by inoculation of the cultures had succeeded in producing acute eczema. Every practitioner was familiar with the auto-inoculability or transmissibility of the disease from one part of the patient's skin to another, and there was also clinical evidence of its contagiousness. Jameson, for instance, had pointed out that in nurses who carry children affected with eczema of the nates the disease was often inoculated in the arms, and instances of the transmission of seborrhœic eczema by contagion have also been recorded. In reference to seborrhœic eczema Leredde, though fully supporting the parasitic theory, held that Unna's description of it was too comprehensive, including as it did seborrhœa, numerous lesions of the pityriasis type, and other lesions called by Unna "yellow spots," which neither on bacteriological nor histological grounds should be classed as eczema. Stripped of these extraneous elements seborrhœic eczema was, in the opinion of Leredde, still a parasitic disease, but not a pure eczema. Leredde believed this malady to be a mixed infection due to the association of a variety of microbes, such as those of fatty seborrhœa, of pityriasis of the scalp, and of certain micro-organisms which were agents in the production of acne, together with a morococcus which was the parasite of eczema. Nevertheless, in view of the facts mentioned Mr. Morris held it proved that parasites were capable of producing eczema, even if it were not actually a parasitic disease. The fact that the most effective remedies against it were of the parasiticide class was of itself a strong argument in favour of that view, but whether the morococcus or some other parasite or combination of parasites was the sole cause of the mischief was another question. In any case the parasite must have a suitable soil to grow in; it could not strike root on a perfectly normal skin. In fact, therefore, predisposing conditions played a very important part in its production, among which might be mentioned certain hard, dry, ichthyosis-like conditions of the integument, the textural changes of old age, previous affections of the skin of long standing (notably the prurigo of Hebra), seborrhœa, and varicose veins, &c., and other causes of inflammatory conditions of the skin, such as irritation caused by certain secretions. Finally, there was undoubtedly in many cases a nervous factor in the causation, a nervous condition which seemed to lessen the resistance of the integument, instances of which were mentioned. This view was also supported by the value in treatment of nerve sedatives such as opium. The statement was generally made by writers on dermatology that eczema was hereditary. This was only true in the sense that phthisis was hereditary, and if the disease existed in one member of a family the others would be favourably placed for receiving infection. As regarded the relation of the general health to eczema the eruption was still regarded by many people as a kind of safety-valve, and patients were often warned that they must bear their skin trouble with such fortitude as they could lest a worse disease befall them in the shape of some other formidable internal disorder. Mr. Morris believed this fear to be absolutely without foundation, though he was prepared to admit that gout, diabetes, Bright's disease, and chronic dyspepsia might be aggravating circumstances, but they were nothing more. They make a case more troublesome to treat but do not cause the disease, or even modify its manifestations in any way which he could trace. In reply to the question what they were to understand by eczema, broadly his reply was as follows: it was a disease the chief clinical character of which was the infinite variety of lesion by which it displayed itself. It originated in the action of parasites on a skin the resistance of which had been enfeebled by pre-existing disease or structural abnormality or by disordered innervation, sometimes made more intractable by gout and other constitutional states, but having no direct relation to the general health.

Dr. COLCOTT FOX (London) said that since the promulgation of Unna's ideas on eczema he had determined to study again the condition known as eczema, unbiased as far as possible by the leanings of his early training. In offering a few observations on the disease in children he said he did so because in them the problem was in a measure free from some of the complications met with in later life. In infants and young children he saw two phases of eczema. The first was the state commonly known as eczema, which began most frequently in infancy on the scalp and descended thence over the face to cover in some instances the greater part of the surface. This eczema was in dry patches at first. Any vesiculation and weeping might, possibly be due to the intensity of the process, but most frequently it appeared to be induced by rubbing and scratching. The second phase consisted of dry, reddish areas, with scanty adherent scales separating along the lines of flexion, but these patches might also when irritated take on a vesicular form indistinguishable from the first phase. This was also a descending inflammation, beginning on the face or scalp as a rule, which he used to call seborrhœa, but that was no doubt a bad term. This was the common affection described by Savill as epidemic amongst children. These phases ran into one another so much that he had constantly the greatest difficulty in separating them. In the next place he could find no cause whatever in the majority of children, for the patients were apparently in excellent health. He did not deny the influence of constitutional disturbance, such as rickets or gastro-intestinal trouble, in increasing the irritation and secondarily spreading and intensifying the inflammation, but the phases of eczema seemed to him to be essentially of local origin. It was possible that the future might disclose varieties caused by various parasites. In studying the disease in adults he was more and more astonished at the number of cases which conformed to the above phases. He did not deny the existence of eczema from constitutional causes, but he seldom met with cases which seemed likely to have such an origin. There was no confirmation of such a theory derivable from the study of eruptions produced by the ingestion of drugs or the circulation in the blood of various serums, or uræmia. At the same time a constitutional state predisposed to the disease, for in a laundry only one woman might have eczema set up by the soda, and this woman might herself be free for years. The soda only set up eczema under certain conditions. He therefore hardly knew on what grounds these occupation eczemas could be separated from the others. Lastly, he thought it extremely likely that the eczematous type of eruption could be produced under the influence of the nervous system. Chemically and anatomically we knew what an eczematous influence was, but no further conclusions seemed possible until further progress was made with the bacteriology of these affections.

In the discussion which followed Dr. WALLACE BEATTY (Dublin), Professor MCCALL ANDERSON (Glasgow), Dr. UNNA (Hamburg), Professor BOECK (Christiania), and others took part, and a general agreement with the views of the opener of the discussion was expressed.

FRIDAY, JULY 29TH.

Dr. P. G. UNNA (Hamburg) gave an interesting demonstration of the various Micro-organisms which he had detected in Impetigo Pustules and of the various Methods he had employed for Staining and Culture of the Organisms.

Dr. COLCOTT FOX (London) and Dr. BLAXALL (London) exhibited a collection of Endothrix Ringworm Fungi. The fundamental classification of the fungi which produce ringworm into the small-spored fungi (microsporon Audouini)

Digitized by Google

and the large-spored fungi or trichophytons is now generally admitted. The former are far more frequently met with in England than the latter and give rise to the most intractable form of ringworm of the scalp, while the latter, though of less frequent occurrence, possess many varieties. Dr. Fox and Dr. Blaxall grouped all trichophytons or large-spored fungi into (*a*) endothrix and (*b*) ectothrix, and the demonstration was given in order to explain the special characters of the former. They also brought forward a paper embodying their Further Researches on Ringworm and its Fungi, with especial reference to the invasion and method of attack of the fungi on the hair. Drawings of stained specimens were shown which demonstrated that the method of attack was essentially similar in all three forms of fungi—viz., the microsporon Audouini, the endothrix, and the ectothrix. This tended to confirm the conclusions formulated by these authors from a study of the fructifications—namely, that all these fungi belong to the same botanical family and that the numerous groups into which they are divided by some foreign authors only constitute them as sub-varieties of one great natural class.

Dr. MORGAN DOCKRELL (London) read a paper on

The Treatment of Skin Sarcoma by Coley's Fluid.

The paper was based on a series of cases, and in general terms the results obtained went to support those of other English observers that the effects of this method of treatment were not so favourable as had been claimed for it by American observers. Up to the present time it was contended removal by the knife or by cautery was the only reliable method, and valuable time might he lost by the use of other means.

Dr. ALFRED EDDOWES (London) read a paper on

The Principles involved in the Treatment of Infected Follicles.

He stated that the hair follicles of the skin might be regarded as elastic tubes guarded by funnel-shaped valves composed of prolongations of the horny layer of the cuticle into their mouths. He had obtained very satisfactory results from the application of a strong solution of phenol when the follicles were inflamed—i.e., in conditions of the follicles characterised by redness at their orifices and a slight tendency to bulge in the form of a minute vesicle, though it was useless for superficial or slack vesicles or for deep infection such as occurred in indurated acne. It was obvious that the larger the amount of fluid contained in the follicle the greater would be the interval between the living tissue and the hair forming the plug and the better would be the opportunity for diffusion to take place. Following this principle in practice Dr. Eddowes attempted in the first place to excite rapid effusion by the application of various liniments and ointments, and before the vesicles had a chance of giving way and thereby releasing the back pressure into the follicle, he applied phenol or other powerful antiseptic.

Dr. DAVID WALSH (London) read a paper on

The Excretory Irritation of the Skin and other Organs.

By "excretory irritation," he said, was meant a directly adverse action upon the epithelium of excretory organs by blood-borne irritants in the process of their excretion. In 1897 he enunciated a series of conclusions,[1] of which the principal were: 1. That some forms of dermatitis were due to the irritation set up by the excretion from the blood of certain specific substances (called by the writer "internal irritants") in the process of their elimination through the skin. 2. That the skin suffered as one of a group of excreting organs and that all these excretory outlets might be similarly affected by internal or blood-borne irritants. 3. That the internal irritants sometimes inflamed the serous and synovial membranes. 4. That proof was afforded, by means of chemical and biological tests, of the frequent passage of some of the internal irritants from the blood into the excretions and into serous and synovial effusions. 5. That any drug which inflamed the skin should be administered with great caution owing to the possibility of damage to other organs. 6. That it might be possible at times to guide the action of a remedy to the particular organ which it was wished to act upon. 7. That conversely any particular organ might be relieved of the stress of elimination. 8. That the law of excretory irritation had a wide application in general pathology. The object of the present communication was to show that recent research had afforded much additional evidence in favour of Dr. Walsh's theory. Arloing[2] had shown the toxicity of the normal sweat. Salter[3] had proved the presence of tuberculin in the sweats of phthisical patients. Hallopeau[4] regarded toxins as the immediate cause of the great majority of cutaneous eruptions—that is, apart from obvious traumatic or hereditary origins. Neumann of Vienna[5] attributed many rashes to the direct action of toxins on the skin and claimed that drug eruptions are due solely to their chemical action upon the skin. Kaposi[6] said that many toxic erythemata were due to the cutaneous excretion of toxins. Bouchard attributed certain rashes associated with dilated stomach to direct toxic elimination. Queirolo of Milan and von Eiselberg of Berlin supported the theory of toxic irritation. The elimination of the actual microbes by the skin had been asserted by Leloir, Singer, Gaertner, Brunner, Babès, and others. Dr. Walsh contended that the foregoing views afforded strong testimony in support of his theory advanced in 1890[7]—namely, that some forms of dermatitis might be due to the excretory irritation—(*a*) of micro-organisms; (*b*) of bacterial products; (*c*) of drugs; and (*d*) of the chemical virus of various specific diseases—e.g., gout.

Mr. THELWALL THOMAS (Liverpool) read a paper entitled Notes of Three Cases of Syphilis communicated by Tattooing.

THE ANNUAL MUSEUM.

(Concluded from page 457.)

V.—MINERAL WATERS, BEVERAGES, ETC.

This interesting section of the museum now comprises table waters, artificial and natural mineral waters, and natural waters of the purgative saline type. One of the most prominent exhibits, and one which was very tastefully and attractively arranged, was that of the Kronthal Company (66, St. James-street, S.W.) near the exit door. There were three types of water shown, all drawn from the Kronthal valley in the Taunus. The table water distinguished by a blue label is a pure, sparkling liquid which contains a trifling proportion of alkaline carbonates and salts, both of which, however, are natural constituents of the water of the spring. We have already reported upon this water in our analytical columns. It is very palatable and brisk and has distinct acid neutralising properties. It is a valuable and natural product possessing pleasing characters which are missing in artificially prepared carbonated water. The Kronthal water distinguished by a red label is decidedly alkaline and saline, so that the statement that it is of benefit in gout and uric acid tendency is not without probability. Experiments are mentioned showing that this water dissolves six times as much uric acid as the purest distilled water. Lastly, Kronthal water distinguished by a yellow label is ferruginous and, moreover, contains the iron in a permanent form notwithstanding the ferrous condition. Most natural waters have a tendency to deposit the iron contained in them, but this water is apparently an exception to the rule, and considering the form in which the iron occurs the water should be valuable in bloodless conditions. Messrs. Ingram and Royle presented a well-arranged exhibit of waters for which they hold an agency. Amongst these was the now well-known Barium Water from the Llangammarch Wells, Wales, which has already been analysed in THE LANCET Laboratory and reported upon, but it is interesting to note that this water has been found to be very distinctly diuretic and of value in gouty tendency and in cases of an excessive quantity of uric acid in the urine. Specimens of the water were presented for inspection and trial both in the still and the aerated form. Connected with the spring at Llangammarch are a well-appointed hotel and baths with accommodation for patients, and there is a resident physician. As is now well known barium water has been employed with very encouraging results in certain cases of cardiac disease. On the same stall were the well-known waters of the State Springs, Vichy, comprising "Celestine" used in kidney disease, diabetes, and gout; "Grande-Grille," useful in hepatic diseases; and "Hôpital," a sedative in gastric disorders. The natural Carlsbad salts prepared from the

Digitized by Google

Sprudel spring formed another feature of this exhibit, while the rest of the space allotted was devoted to the now well-known natural bitter aperient water Hunyadi János. Evidence of the enterprise which has recently been shown in connexion with the development of the Royal Leamington Spa, Warwickshire, was afforded in the interesting series of specimens exhibited at the stall representing this Midland health resort. The display consisted chiefly of bottled, aerated, and concentrated waters from the natural mineral springs. In presenting some important differences in composition from many other natural aperient waters Condal Water is of interest. It contains, as we have previously shown in our analytical columns, sulphate of soda and sulphate of magnesia, the proportion of the former to the latter being as 10 is to 1. The Condal Water Company, 38, Walbrook, E.C., take every measure to guarantee that the water bottled is exactly the same as the spring yields. A great number of various artificially aerated waters was shown on the well-arranged stall of Messrs. Jewsbury and Brown (Manchester). In addition to the ordinary mineral waters there was Effervescing Kola and, as medicated waters may be mentioned Lysidine Water, Piperazine Water, Aerated Lime Water, and Carrara Water. Messrs. Alexander Riddle and Co. (36 and 38, Commercial-street, E.) found space mostly for the exhibition of Stower's Lime Juice Cordial and Lemon Squash, both of which afforded satisfactory results on analysis on the occasion of a laboratory examination which we made some time ago. In addition they offered what is described as "a perfect table water," while specimens of the Marie and Elisabeth springs of Vichy were also shown. An exhibit which attracted considerable attention was that of Aerators, Limited (Broad-street-avenue, E.C.). We have described the invention before, but so interesting and important is its application likely to become that we may append further particulars. A strong bottle is provided into the bulb-shaped neck of which is placed a "sparklet" or small steel bomb containing liquid carbonic acid gas. On screwing home the stopper the bomb is pierced and in a short time the water is thoroughly charged with the gas thus set free. This invention promises many useful applications amongst which may be mentioned the aeration of milk without dilution. A model of the methods of treatment at Harrogate was shown by the municipality of that town and the well-known natural waters of this well-known health resort were exemplified in bottled specimens of strong and mild sulphur water, chloride of iron water, and saline iron water. An interesting group of residual salts from the springs was also shown. The stall of the Apollinaris Company, Ltd. (4, Stratford-place, Oxford-street), was very large and well arranged, the space being crowded with the well-known natural waters now associated with the name of this company. Thus there were Apenta Water, a natural bitter magnesia water, Friedrichshall Water (which is also aperient, but which in addition is rich in alkaline chlorides), and Apollinaris Water and Johannis Water (the characters and properties of these table waters, as is well known, being similar to each other). Lastly, we may mention, as a convenient means of preparing an excellent, wholesome, and refreshing beverage, Specialité Lime Juice Cordial and Lemon Squash, possessing all the fresh aromatic flavour of the new and ripe fruit. An interesting addition to this exhibit was a Lemon Squash in the form of concentrated juice reduced to a crystalline residue. They are prepared by Messrs. Feltoe and Smith, 25, Augustus-street, Regent's-park, N.W.

VI.—PUBLICATIONS.

As might be expected in a city where there are several well-known publishers of medical books there was a larger display than has been usual on previous occasions of recent medical literature and publications. A complete list of books of comparatively recent issue occurred in the catalogue of the exhibition. We need only mention that the following well-known publishing firms were represented: Mr. Y. J. Pentland (Edinburgh and London); The Rebman Publishing Co., Ltd. (129, Shaftesbury-avenue, Cambridge-circus, W.C.) — this firm in addition exhibiting pure calf lymph in tubes and a system of rapid analysis by thermometer which is applicable to urea, ammonia salts and alcohol, according to the experiments of Mr. Barker Smith; Mr. B. Allsop (*Times* Office, Shipley Yorks) showed the A.B.C. system of medical book-keeping, a method now indispensable to the methodical and careful practitioner. Another system of medical book-keeping and one which presents distinct advantages was that shown by Messrs. G. C. Veale and Co. Further may be mentioned amongst booksellers Mr. W. Bryce (54, Lothian-street, Edinburgh); Messrs. Baillière, Tindall, and Cox (London); Messrs. Cassell and Co. (London); Mr. W. F. Clay (18, Teviot-place, Edinburgh); Mr. J. Craig (1, Pink-lane, Newcastle-on-Tyne), who represented Mr. H. Kimpton (82, High Holborn, W.C.); and Messrs. J. Wright and Co. (Bristol).

VII.—MISCELLANEOUS.

In this paragraph we may include those exhibits which it is difficult to classify except under the above heading. Perhaps the oddest thing in this connexion, though we are far from saying that it was not fully entitled to a place, was the improvement in domestic grates shown by Mr. David Melville (136, High-street, Edinburgh). There is certainly merit in these stoves, as while they effect an important economy in coal consumption they give a more satisfactorily distributed heat, consuming cinders, obviating dust, and promoting a uniform circulation of the air. The uses and application of the Ceres Automatic Letter and Card Files were explained to the visitors by the Ceres Depôt Co. (16, Brook-street, W.). The inventor and patentee is Mr. T. Bowater Vernon. The Edinburgh School of Shorthand and Typewriting (40, Shandwick-place, Edinburgh) took the opportunity of showing the Williams Typewriter (agency, 104, Newgate-street, London). It is described as giving visible writing, having no ribbons, being of simple construction, and a very good manifolder and very portable. Some excellent photographs were presented to view by Mr. A. Swan Watson, the official photographer to the exhibition, of New Park Studios, Bruntsfield Links. Under this heading also should be mentioned the Aseptic Glycerinated Calf Lymph of the Jenner Institute (73, Church-road, Battersea, S.W.), which is stated to be prepared in strict accordance with the methods advocated by the Local Government Board. This exhibit was instructive inasmuch as a series of plate cultures was shown illustrating the destructive influence of glycerine on adventitious microbes.

[Under the section of Foods and Food Products we omitted to mention the Invalid Specialities of Mr. Benoist (36, Piccadilly, W.), which were exhibited by Mr. H. Lawrence (47, Strand, London). The excellent Turtle Soup for invalids has, however, quite recently been the subject of favourable criticism in our analytical columns. The exhibit also included Soups and Potted Meats prepared by Mr. C. Shippan of Chichester.]

BRISTOL SEWAGE.—For several months the question of dealing with the sewage of Bristol has been under the consideration of a sub-committee appointed by the Bristol Sanitary Authority. The engineers who have been consulted recommend a scheme which provides for an outfall near Dunball Island and for the construction of storage tanks at Avonmouth so that the discharge may be effected at suitable states of the tide. A new sewer will be constructed following the course of the River Avon on the Gloucester side and a pumping-station will be erected to lift the sewage into the outfall sewer whence it will be conveyed to the Bristol Channel. The cost of the scheme will be between £300,000 and £400,000 and it is said to be sufficient for a population of 500,000. The formal report upon the matter has yet to be presented to the Sanitary Committee.

BOLINGBROKE HOSPITAL.—The annual report of Bolingbroke Hospital, Wandsworth-common, S.W., shows that during 1897 there were 300 patients treated in the hospital, comprising 49 medical cases (with 4 deaths) and 251 surgical cases (with 19 deaths); 97 surgical operations were performed. In the accident room 9138 patients were attended, of whom 179 were so seriously injured that they had to be admitted as in-patients. There were 291 cases of fracture. In the out-patient throat and ear department there were 717 attendances of patients sent with recommendations from medical men. The accounts show that the total ordinary income for the year was £3157, including £981 of in-patients' payments, while the total ordinary expenditure was £3184. The hospital premises were originally a private house which Canon Erskine Clarke, the vicar of Battersea, with the aid of subscriptions, bought and fitted up as a self-supporting hospital about 17 years ago. In 1897 it was incorporated and thus put on a permanent footing as a home hospital and a free accident hospital. The committee make an earnest appeal for financial support.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* Dr. Hochhalt has been recognised as *privat-docent* of Internal Medicine, Dr. S. Gerlóczy as *privat-docent* of Infectious Diseases, Dr. Ludwig Nékam as *privat-docent* of Dermatology, Dr. L. Makara as *privat-docent* of Operative Medicine, and Dr. Heinrich Alapy as *privat-docent* of Diseases of the Urinary Organs.—*Cracow:* Dr. Vladimir Sieradzki has been recognised as *privat-docent* of Forensic Medicine.—*Giessen:* Dr. Hans Koeppe has been recognised as *privat-docent* of Physiology.—*Jena:* Dr. Ernst Hertel has been recognised as *privat-docent* of Ophthalmology.—*Munich:* Dr. H. Rieder has been appointed Extraordinary Professor of Hydro-therapy and Electro-therapy.—*Parma:* Dr. Gerolamo Gatti of Padua has been recognised as *privat-docent* of Surgical Pathology.—*Poitiers:* Dr. Malapert has been appointed Professor of Surgical Pathology and of Operative Medicine.—*Prague (Bohemian University):* Dr. Karl Svehla has been recognised as *privat-docent* of the Pathology and Treatment of Children's Diseases.—*Rome:* Dr. Alessandro Regnoli has been recognised as *vrivat-docent* of Midwifery and Gynæcology.

TEIGNMOUTH INFIRMARY.—The fifteenth annual report of the Teignmouth Infirmary has recently been published. It shows that during 1897 there were 162 in-patients admitted and 1662 out-patients treated, being an increase on the previous year. Unfortunately the receipts show a diminution of about £60.

THE LATE DR. A. P. SMITH OF BALTIMORE.—The *Maryland Medical Journal* of July 30th states that in the death of Dr. Alan P. Smith the medical profession of Baltimore has lost a surgeon who was the leading lithotomist of the country. He was born in 1840 and after receiving his academic education at Princetown he returned to Baltimore and entered on the study of medicine at the University of Maryland. In 1863 he was appointed adjunct professor of operative surgery in the University, and he occupied the chair of operative surgery from 1873 to 1877, when he retired to devote his whole time to private work. His surgical work included a series of 52 operations for lithotomy without a death.

THE FITZWYGRAM PRIZES TO VETERINARY COLLEGES.—The results of the open competition for the prizes given by General Sir Frederick Fitzwygram, Bart., M.P., for students in the four veterinary colleges of Great Britain, have just been announced. The first prize, value £50, has been gained by Mr. W. Jowett, M.R.C.V.S., a graduate from the New Veterinary College, Edinburgh, and the second prize, value £30, has been gained by Mr. T. Wolsey, M.R.C.V.S., a graduate from the Royal College of Veterinary Surgeons, London. The students of the New Veterinary College have been unusually successful in this, the most important examination open to veterinary graduates.

OPENING OF A NURSING INSTITUTE.—On August 9th the Bishop of Wakefield (Rev. Dr. Eden) opened a nursing institute at Cawthorne, a village about 4 miles from Barnsley. The building was formerly the chapel of the Wesleyan Methodists of Cawthorne and will henceforth be known as the Victoria Cottage Institute, an inscription over the doorway stating that it was appropriated to its present purpose in commemoration of the Queen's sixty years' reign. The district nurse will reside on the premises and it is intended that in winter time instruction in cookery will be given to the girls of the neighbourhood; a room has also been specially provided for the holding of mothers' meetings. The institute will be managed by a committee of ladies, presided over by Mrs. Montague Spencer Stanhope, the principal promoter of the undertaking.

RAILWAY EXTENSION TO BUDE.—The extension of the London and South-Western Railway from Holsworthy to Bude was formally opened on August 10th. The directors of the company were received at the station by Mr. John King, M.R.C.S. Eng., L.R.C.P. Edin., J.P., and the Rural District Council presented an address alluding to the beauties of the district. Bude is now easy of access from London and its advantages as a health resort ought to attract visitors.

MEDICAL MAGISTRATES.—The Lord Chancellor has added to the commission of the peace for the borough of Penzance the names of William Shepheard Bennett, M.R.C.S. Eng., and John Symonds, M.R.C.S. Eng., L.S.A. Lond.—Mr. James K. Kerr, M.D. R.U.I., of Glenaltans, Knock, Belfast, has been appointed a magistrate for the petty sessions district of Belfast.

VACCINATION AT FALMOUTH.—At the meeting of the Falmouth Board of Guardians held on August 11th it was stated that the vaccination returns for the Falmouth and Constantine districts for the first half year of 1897 showed that there were 184 births of children, of whom 154 were unaccounted for.

CARDIFF INFIRMARY.—At a meeting of the committee of the Cardiff Infirmary held on Aug. 10th it was decided that a gynæcologist to the institution should be appointed immediately.

LITERARY INTELLIGENCE.—Messrs. Macmillan and Co. have just ready for publication "A Clinical Treatise on Diseases of the Breast," by Mr. A. Marmaduke Sheild, senior assistant surgeon of St. George's Hospital.

Digitized by Google

VACCINATION AT GLOUCESTER.—At the last weekly meeting of the Gloucester Board of Guardians it was stated that during the half year ended December last there had been 820 children born, of whom 81 were successfully vaccinated, 99 died unvaccinated, and 559 were defaulters.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Close of the Session.

THE session of Parliament which opened on Tuesday, Feb. 8th, was brought to a close on Friday, August 12th. For medical men the measure of most interest dealt with during the session was the Vaccination Bill brought in by Mr. CHAPLIN and passed with the important amendment giving those who entertain conscientious objections to vaccination an opportunity of stating their objection and taking certain proceedings and thus avoiding prosecution for default. In this connexion it is of some importance to remind our readers that while the Bill was before the House of Lords the Government undertook to consider the question of revaccination during the recess with a view to future legislation. Other measures of special interest to the medical profession passed during the session were a Bill to set up a teaching university in London, a Bill to provide for the better treatment of inebriates of the criminal class, and a Bill amending in one or two particulars the Pharmacy Acts. Late in the session the Government introduced a Bill dealing with the sale of poisons, but neither it nor Mr. Chaplin's Bill to put down the adulteration of food products was carried. The prorogation was performed as is usual by a Royal Commission consisting of Members of the House of Lords.

The Plague in India.

The Queen's Speech at the close of the session contained the following paragraph—viz.: "In certain portions of Western India, and in a small district of the Punjab, the plague, though it has abated during the hot weather, still exists, and a few cases have occurred in other parts of the country. My officers have done all that lies in their power to relieve the victims of the epidemic and to arrest its growth. I am thankful that bountiful harvests have been gathered throughout the greater part of India and that the internal and external trade of the country is rapidly recovering from the depression caused by the famine of the preceding year."

HOUSE OF COMMONS.

THURSDAY, AUGUST 11TH.

Bacteriological Investigation in India.

Mr. HERBERT ROBERTS asked the Secretary of State for India whether he was aware of the proposal to found a bacteriological institute in India; whether he would state whether the Government of India had sanctioned the project and if so to what extent were they committed; whether the funds for this project were being raised by subsciptions from Indian princes and to what extent had this been done; whether he would state whether it was intended that experiments on animals should be carried on under this project; whether the institute was designed as a memorial of the Diamond Jubilee of the Queen; and whether, having regard to the divergence of views in reference to such an institution, he was in a position to recommend as a memorial of Her Majesty's Jubilee in India some work of benevolence commanding general support.—Lord GEORGE HAMILTON replied: I am aware that the Government of India have had before them proposals for the foundation of a Pasteur institute to which a bacteriological laboratory would be attached. Such institutions have to be almost entirely supported by private subscription. Independently of this project the Government of India have had under their consideration the advisability of establishing an institution for the bacteriological investigation of certain diseases specially prevalent in tropical climates. No information has reached me which justifies the assumptions and suggestions of the last three questions.

The Preparation of Tuberculin.

Mr. CHANNING asked the President of the Local Government Board whether, having regard to the recommendations of the Tuberculosis Commission and the necessity of having a pure, uniform supply of tuberculin of uniform quality for those who might wish to use it for testing their herds or dairies, he would have arrangements made at the Local Government Board Laboratory for the preparation of a limited supply of pure tuberculin.—Mr. WALTER LONG, replying for Mr. Chaplin, said that the Local Government Board could not make any such arrangements as those suggested in the question.

Venereal Disease in the Army in India.

During the debate on the Indian Budget, Mr. JAMES STUART raised this question and got a reply from the SECRETARY OF STATE FOR INDIA, who said that the hon. member must recollect that when the present Government came into office they found a most remarkable and almost incredible state of things. A certain body of ladies and gentlemen, with the desire of promoting social purity and public morality, had actually contrived in their zeal that it should be enacted in India that venereal disease should be the only disease which should be exempted from the regulations and restrictions applicable to all other contagious diseases. The condition of things seemed to him absolutely intolerable. He had always looked on this not as a military but as a national question. They had to promote the health of the people. They had a magnificent army in India—an army capable of great performances. It must not be forgotten that during the past two years our soldiers in India had distinguished themselves on the frontier and elsewhere. These soldiers were all more or less young soldiers and when the *Warren Hastings* transport was in danger many of these young soldiers stood for hours in a sinking ship and not one of them moved until every woman and child on board was removed. Therefore, he said, they were young men full of chivalrous instincts towards the weaker sex, and he did think it was an absolute disgrace that a condition of things should be allowed to exist in India whereby this superb army should become a sewer for the transmission of the worst of contagious diseases. They thought it was necessary to try to do something to mitigate the ill effects which had existed, and what they proposed was simply to put venereal disease on exactly the same footing as other contagious diseases. He expressly laid down certain conditions which should not be infringed. As a natural consequence of their determination they had to repeal the Act which prevented this disease from being put on the same footing as other contagious diseases. He had taken the utmost care to test the accuracy of the figures relating to India and he could assure the hon. Member that there was indisputable evidence to show that the removal of all regulations had largely increased the disease in India and that its intensity had also been greatly augmented. Certain reforms had been suggested and adopted relating to inspection and to measures for preventing the concealment of disease. Again, memoranda had been issued by the Commanders-in-Chief, both in India and at home, impressing upon regimental officers the necessity of giving good advice to young soldiers, pointing out the evil consequences which ensued from giving way to vicious habits and directing that in the recommendations for promotion care should be taken to see that those selected were free from vicious habits. It would be seen, therefore, that not only had he kept faith in everything he had undertaken to do, but he had gone even beyond it. He looked upon this question as one of national importance and one which must not be looked at from a purely political point of view. He believed the regulations which had been laid down could, from every aspect, be justified, that they were in accordance with the Christian precept which exhorted them to heal the sick, and that they were dictated by the common principles of humanity.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

APTHORP, HUGH L., M.B., C.M. Edin., has been appointed Assistant House Surgeon for the Devonshire Hospital and Buxton Bath Charity, Derbyshire.

BALL, C. B., M.D., M.Ch., F.R.C.S. Irel., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County of Dublin and for the Borough of Dublin.

BARRIE, W. J., M.B., C.M. Edin., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County of Roxburgh.

BELL, J. B., M.B., C.M. Edin., has been appointed Medical Officer of Health by the Cults Parish Council.

BOWDEN, W. J., M.B., Ch.B. Vict., has been appointed Medical Officer for the Glossop Sanitary District of the Glossop Union.

BURBIDGE, J. W., L.R.C.P., L.R.C.S. Edin., has been re-appointed an Honorary Surgeon for the Lewes Victoria Hospital.

BURY, E. C., M.D. St. And., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Wisbech Union, vice J. C. Bury.

COLEMAN, M. O., M.D. Aberd., M.R.C.S., D.P.H., has been re-appointed Medical Officer of Health by the Surbiton Urban District Council.

CROSSKEY, W. F., M.D., C.M. Glasg., has been re-appointed an Honorary Consulting Surgeon for the Lewes Victoria Hospital.

DOW, W. A., M.D. Durh., L.R.C.P. Lond., M.R.C.S., D.P.H., has been re-appointed an Honorary Surgeon for the Lewes Victoria Hospital.

FALVEY, F. J., L.R.C.P., L.R.C.S. Edin., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Kerry.

FAWSSETT, F., M.B. Lond., B.S., L.R.C.P., M.R.C.S., has been re-appointed an Honorary Surgeon for the Lewes Victoria Hospital.

FLETCHER, J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Hoxne Sanitary District of the Hoxne Union, vice J. D. Phillips.

FRASER, H., M.B., C.M. Aberd., has been appointed Medical Officer of Health by the Harpenden Urban District Council.

HALL, F. A., L.R.C.P. Lond., M.R.C.S., has been re-appointed an Honorary Medical Officer for the Lewes Victoria Hospital.

HANLY, J. J., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Fifth Sanitary District of the Wells Union.

HARRISON, HERBERT, M.R.C.S. and L.R.C.P. Lond., has been appointed House Surgeon for the Devonshire Hospital and Buxton Bath Charity, Derbyshire.

HOOPER, C., M.R.C.S., has been re-appointed Medical Officer of Health by the Aylesbury Urban District Council.

Digitized by Google

HOWE, A. F. A., L.D.S., has been re-appointed an Honorary Dental Surgeon for the Lewes Victoria Hospital.

JONES, T. E., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer, *pro. tem.*, for the Amlwch Sanitary District of the Anglesey Union, vice G. G. Jones, resigned.

KILLICK, C. R., M.B. Lond., L.S.A., has been appointed Medical Officer of Health by the Williton Rural District Council.

KINKEAD, R., M.D., L.R.C.S. Irel., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County and the Borough of Galway.

LOUD, F., L.R.C.P. Lond., M.R.C.S., has been re-appointed an Honorary Surgeon for the Lewes Victoria Hospital.

MACDERMOTT, P. A., L.R.C.P., F.R.C.S. Irel., has been appointed an Assistant Surgeon to the Dublin Metropolitan Police.

MELDON, A., M.R.C.P., F.R.C.S. Irel., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County of Dublin and for the Borough of Dublin.

MOIR, J. M., M.D. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County of Inverness (main land).

PEARCE, J. P., M.R.C.S., has been re-appointed an Honorary Surgeon for the Lewes Victoria Hospital.

PRATT, JOS. D., M.D., B.Ch. Dubl., F.R.C.S. Irel., has been appointed an Assistant Surgeon to the Dublin Metropolitan Police.

REVELY, JOS. S., M.D. Durh., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Tettenhall District of the Seisdon Union, vice F. J. Hawthorn.

RICHARDS, W. H., M.B., B.S., L.S.A., has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, S.W.

RUSSELL, J., M.B., C.M. Glasg., has been re-appointed Medical Officer of Health by the Brigg Urban District Council.

SMYTHE, L., M.D. Glasg., F.R.C.S. Eng., has been re-appointed an Honorary Consulting Surgeon for the Lewes Victoria Hospital.

SPICER, ARTHUR H., M.B., B.S., M.R.C.S., has been appointed Registrar to the Chelsea Hospital for Women, Fulham-road, S.W.

WILKES, E. M., L.S.A., has been appointed Medical Officer for the Second Sanitary District of the Parish of Battersea in the Wandsworth and Clapham Union.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

CARDIFF INFIRMARY. — Assistant House Surgeon for six months. Salary at the rate of £50 per a num, with board, washing, and apartments.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, increasing £10 yearly to £120 per annum, with board, lodging, washing, and attendance.

COUNTY ASYLUM, Gloucester.—Locum Tenens for about two months. Salary £2 2s. per week and all found (except liquors).

CUMBERLAND INFIRMARY, Carlisle.—Assistant House Surgeon for seven months from Oct. 1st to April 30th. Salary at the rate of £40 per annum, with board, lodging, and washing. Also House Surgeon for one year. Salary £70 per annum, with board, lodging, and washing.

DEVON COUNTY ASYLUM.—Medical Superintendent. Salary commences at £800 per annum, with other emoluments. No domestic or other servants provided. Applications to the Clerk to the Visiting Committee, 9, Bedford-circus, Exeter.

Births, Marriages, and Deaths.

BIRTHS.

BOWDEN.—On August 8th, at University-square, Belfast, the wife of W. J. Bowden, D.D.S., L.D.S., of a son.

DALDY.—On August 16th, at Springfield-road, Kingston-on-Thames, the wife of Arthur M. Daldy, M.D., of a son,

ELLIS.—On August 13th, at Cedar Lodge, Lambridge, Bath, the wife of W. McDonogh Ellis, M.D., M.R.C.S., of a daughter.

GOODCHILD.—On August 8th, at Highgate, N.W., the wife of N. John Goodchild, M.R.C.S., L.R.C.P., of a son.

RABY.—On August 8th, at Craven House, Devizes, the wife of Leonard Raby, M.D., of a daughter.

WINGFIELD.—On August 12th, at Aubyn House, Moseley, Birmingham, the wife of J. Wingfield, L.R.C.P. and L.R.C.S. Edin., of a son.

MARRIAGES.

BUXTON—HAYWARD.—On August 17th, at St. Peter's, Dulwich-common, Alfred St. Clair Buxton, F.R.C.S.E., to Henrietta Blanche, elder daughter of Edward King Hayward, of Marmora-road, Honor Oak.

EDELSTEN—MUSKETT.—On August 10th, at the parish church, Corfe Mullen, Dorset, by the Rev. Eliott-Drake Briscoe, M.A., assisted by the Rev. R. Plumptre, M.A., rector of the parish, and the Rev. F. L. Schreiber, M.A., Ernest A. Edelsten, M.B., M.A. Oxon., M.R.C.S., L.R.C.P., of Brixton, S.W., eldest son of J. Malin Edelsten, Esq., of Grappenhall, Cheshire, to Catherine Helen, daughter of the late John Muskett, Esq., of Diss, Norfolk, and of Mrs. Moon, of Corfe Lodge, Wimborne, and granddaughter of the late John Gould, Esq., F.R.S.

DEATHS.

BAWTREE.—On August 13th, at Mistley Hall, Essex, Edward William Bawtree, M.D., Deputy-Inspector-General of Hospitals, aged 80 years.

HAWKEN.—On August 12th, at Coombe St. Nicholas, near Chard, Charles St. Aubyn Hawken, M.R.C.S., formerly of Wandsworth, Surrey.

LEWIS.—On August 13th, at Markham Lodge, Liverpool-road, Kingston-on-Thames, Deputy Surgeon-General John Riggs Miller Lewis, aged 77.

ROPER.—On August 14th, at Southwold, Suffolk, George Roper, M.D., formerly of Ovington-gardens, S.W., aged 75.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898, bound in cloth, gilt lettered, price 18*s.*, carriage extra; and Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*, can be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.

Subscriptions which may commence at any time) are payable in advance.

"TUMOURS CAUSED BY PATHOGENIC YEASTS."

AT a meeting of the Society for the Cultivation of Medical and Natural Science in Cagliari, reported in the *Supplemento al Policlinico* of July 16th, Professor Sanfelice said that in his experience when dogs were inoculated with material obtained from malignant tumours occurring either in man or in the lower animals there was either no pathogenic action at all or else only inflammatory processes which had nothing in common with the tumours from which the inoculations were made. This could be easily explained on the ground of the alterations which the blastomycetes undergo in the production of chronic lesions such as tumours. He therefore abandoned the experimental inoculations with the products of morbid growths and applied himself to the study of saccharomyces neoformans, a blastomyces obtained from the atmosphere, using it for the inoculation of dogs and cats, as these animals are liable to become spontaneously affected with malignant tumours. After inoculations of pure cultures of saccharomyces neoformans, if the duration of the infection was long the "parasites" always assumed the typical forms described by Russell as fuchsin corpuscles and by other observers as coccidia, and nothing was found to support the views of those who maintain that Russell's corpuscles are due to a degeneration of the cellular elements. Among a great number of inoculations made specially on dogs two have recently yielded positive results and have convinced him that the saccharomyces neoformans is capable of producing in dogs tumours which both in their growth and structure are identical with adenocarcinoma in man. This view is in direct opposition to that expressed by Dr. Busse, quoted in THE LANCET of August 6th.

HOSPITALS IN ANCIENT TIMES.

THE *Scientific American* is responsible for the following:—

"A very interesting and pleasing discovery is announced from Baden, near Zürich. The learned have been discussing for ages whether anything in the way of hospitals was known to the ancients—it is not to be said that they have been disputing, for there was not material enough hitherto to support a lively argument. One might read the whole volume of Greek and Roman literature—carefully, too—without noticing one passage that might be interpreted as an allusion to a hospital. The works of Hippocrates could not fail to speak of them surely, if any existed; but nothing is there beyond a reference to the notes of 'cases' observed in the Temple of Æsculapius. So it is generally assumed that there were no hospitals in those days; the Aesclepia were 'baths' with massage treatment. Scholars who hold to the other opinion can adduce only hints in its favour. But now we hear that one has actually been discovered at Baden, containing 'fourteen rooms, supplied with many kinds of medical, pharmaceutical, and surgical apparatus, probes, tubes, pincers, cauterising instruments, and even a collection of safety pins for bandaging wounds'—but these things are familiar. 'There are also medicine spoons in bone and silver, measuring vessels, jars, and pots for ointment, some still containing traces of the ointment used.' The latest date of the coins found appears to be in the reign of Hadrian. Probably it was a military hospital, for this was the station of the Seventh and Eighth Legions. But the find is certainly not less interesting on that account, for the army medical service of Rome and Greece is one of the deepest mysteries of archæology. Cæsar refers only once to his regimental surgeons—is there a single distinct allusion elsewhere? We hail with puzzled gratitude the casual remark of Xenophon that the Spartans sent their doctors to the rear when a fight impended, but we look vainly for more information from him or anybody else."

THE CASE OF DR. REICHARDT.

DR. SAVAGE sends us the following list of subscriptions which have been received towards a fund for Dr. Reichardt's defence:—

WANTED A TRACT ON SIGHT-TESTING.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me of a brief tract on the subject of spectacles which can aid me? For four years past I have used a double eye-glass (numbered 16) which suddenly appears unsuitable. Opticians have supplied me with others (No. 15, &c.), which, however, hardly appear to suit as well as my old one. I am aware I have been reading rather too much, but I feel convinced that I have not got the proper lens. It is difficult for me to visit an oculist. There ought to be some pamphlet, not of a mere catchpenny order, instructing a physician how to gauge his own sight or that of others, and if you personally know of such of real value I should be very much obliged for the information.

I am, Sirs, yours faithfully,

August 15th, 1898. FUNDUS OCULI.

THE GENERAL PRACTITIONER AND HIS FEVER PATIENTS.

To the Editors of THE LANCET.

SIRS,—As a general practitioner I am anxious to lay the following case before you. I was treating a patient who happened to be a great supporter and friend of mine, and finding he suffered from typhoid fever I reported the case to the medical officer of health, whereupon he had him removed to the sanatorium. A few days after I naturally thought of calling to see my former patient and friend, so I wrote letting the medical officer of health know that I was anxious to call and hoping he had no objection. To my surprise he wrote telling me he could not permit me to visit the sanatorium unless my patient got worse, when

Digitized by Google

he would call me in consultation. In reply I expressed my surprise and explained that I intended calling, not in any professional capacity, but as a friend. To this, however, I got no reply, but the patient died, and I was not even called in consultation. Do you not think that the medical officer of health might have allowed me to visit the patient a few times as a friend, or if he so objected, might he not have offered me to accompany him on one or two of his morning visits, knowing that I was most anxious to see him, or, finally, as he suggested himself but did not carry out, should he not have asked me in consultation? I must apologise for taking up so much of your space, but I am anxious to give you full particulars as the above case and similar ones place me in a very awkward position, since when my patients are removed to the sanatorium many of them expect that I should call to see them a few times during their sojourn there.

I am, Sirs, yours faithfully,

August 15th, 1898. GENERAL PRACTITIONER.

*** The Local Government Board has always urged that the medical officer of health should be careful to regulate his conduct towards the general practitioner by the customs which usually govern the relations of medical practitioners towards each other. [See "Difficulties under the Infectious Disease (Notification) Act," a small pamphlet published at this office.] But a medical officer of health often finds it difficult to discharge his duties towards the public and comply at the same time with a rigid interpretation of the demands of medical etiquette. It seems to us unfortunate from the above account that our correspondent was not allowed to see his former patient, but we cannot express a definite opinion upon a one-sided statement.—ED. L.

THE NOMENCLATURE OF SKIN DISEASES.

To the Editors of THE LANCET.

SIRS,—In your account of the Dermatological Section at the Edinburgh meeting of the British Medical Association in THE LANCET of August 13th, p. 455, column 1, the following statement occurs: "Formerly everything bullous was called pemphigus, but owing to the researches of Unna, Duhring, and others, a new group named dermatitis herpetiformis has been sorted out from the pemphigus class ....." As a matter of fact, it was the late Tilbury Fox who first drew attention to hydroa herpetiforme, or dermatitis herpetiformis as it is more usually called, in 1880 (*vide* Diseases of the Skin by H. Radcliffe Crocker, second edition, p. 204). This point was well brought out at the discussion on Dermatitis Herpetiformis by the Dermatological Society of London (*British Journal of Dermatology*, March and April, 1898). I am, Sirs, yours faithfully,

GEORGE PERNET.

Upper Gloucester-place, N.W., August 15th, 1898.

Mr. E. S. Gooddy.—1. It is difficult to say when a cottage hospital becomes a general hospital. To put it shortly, we should say that a cottage hospital was (*a*) small—e.g., 20 beds; (*b*) strictly local; (*c*) that it had no staff of its own, but that each medical man who sent a patient to it had the right to attend such patient.—2. "Neale's Digest" may be consulted for full references. We may mention an article in the *Practitioner*, vol. ii., 1893, and another in THE LANCET, Oct. 13th, 1894, p. 847.

Chirurgus.—If there is any legal bond our correspondent is, of course, legally bound to abide by that bond. If there is no bond there are still considerations of honour to be looked to, but we should say that in a town of such a population as our correspondent mentions if he took care to avoid taking over any patients whom he knew had previously belonged to the practitioner whose work he had done there would be no harm in the course which he proposes to adopt.

E. P. N.—The General Medical Council issued separate summonses against the practitioner in question, one for calling himself a "physician" and another for calling himself a "surgeon," but the latter summons was not proceeded with. A holder of the diploma in question is entitled to compete for appointments in the navy, the army, or under the Poor-law.

Mr. James Downing.—THE LANCET has never recommended either the Mattei or Viavi treatments. With regard to them, however, we may refer our correspondent to our issues of Jan. 19th, 1895, p. 174, and Jan. 31st, 1896, p. 181.

F.R.C.S. Eng.—We do not consider the communication quite suitable to our columns and we cannot take the responsibility of advising that it should be sent to the eminent nobleman upon whose words it is founded.

Mr. G. Dundas Edwards.—No one can practise on French soil unless he possesses the degree of M.D. of a French faculty. All information as to the question will be found in THE LANCET, Sept. 12th, 1896, p. 769.

H. de B. D.—The circulation of such a card is contrary to professional etiquette, and the circumstances are made worse by the fact of the card being left at the house of the patient of another practitioner.

J. W. H.—The high centre of the county, the rigorous east and north coast and the marshy south and west borders differ entirely in their suitabilities for such patients.

Ablution.—There are several, and their tariffs vary considerably and not always directly as the comforts afforded. A list will be found in the Post-office Directory of London.

C. A. R.—We have no further information. The medical view is definite enough and our correspondent has expressed it correctly.

H. F. W. (Aldershot).—It would be an undoubted transgression of medical etiquette.

Religieuse should consult her medical adviser.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Presidential Address
ON
THE PUBLIC HEALTH OF DUBLIN.

Delivered at the Congress of Public Health, held under the auspices of the Royal Institute of Public Health, at Dublin, August 18th to 23rd,

BY SIR CHARLES A. CAMERON, M.D. R.U.I., D.P.H. CANTAB., M.R.C.P. IREL., F.I.C.,

EX-PRESIDENT; PROFESSOR OF HYGIENE AND CHEMISTRY, ROYAL COLLEGE OF SURGEONS IN IRELAND; MEDICAL OFFICER OF HEALTH OF DUBLIN.

MY LORDS, LADIES, AND GENTLEMEN,—My first duty on this occasion is to express my warmest thanks to the Royal Institute of Public Health for the honour which they have conferred upon me in selecting me to preside at this important Hygienic Congress. It is by no means the only compliment which the Institute have paid me, for I gratefully bear in mind that four years in succession they unanimously elected me to be their President. I esteem this action of the Institute all the more from the circumstance that their headquarters are situated in London whilst I am a resident in Dublin. In the six millions of people in that vast city no difficulty would have been experienced in securing for the presidency of the Institute men of the highest repute in the domain of science. I rejoice to know that under the leadership of my distinguished successors, Sir Henry Littlejohn and Professor Smith, the career of the Institute has been one of uninterrupted success and that at this moment it occupies a high position amongst the many useful organisations in these countries which are supported by voluntary efforts and are without State aid.

My next duty is the pleasant one of welcoming most warmly, on behalf of the Reception Committee of the Congress—and I may, indeed, say on the part of the citizens of Dublin—the visitors who have come to this city from England, Scotland, Wales, and the Irish provinces to take a part in the proceedings of this Congress. Amongst them are the bearers of names known and respected in many lands. They have done noble work in devising and carrying into effect measures for the mitigation of human suffering in disease, for the prolongation of life, and for the amelioration of the conditions under which the lower and more dependent classes of the population exist. In our forthcoming conferences their voices will be heard earnestly and eloquently advocating the adoption of every means by which the moral and physical improvement of our race might be promoted. I use the word moral advisedly, for assuredly the strict observance of the laws of physical health cannot fail to exercise a beneficial effect upon our morals. Truly has it been said that cleanliness is next to godliness, and we cannot forget that the first code of sanitary laws came to us from a Divine source. The lessening of overcrowding in the tenement houses, the better care of the children of the poor, the multiplication of open spaces and recreation grounds, the provision of means of innocent amusements, cheap baths and washhouses, healthful dwellings at moderate rents, are all agents for improving the *morale* and *physique* of the people.

HIGH DEATH-RATES IN TOWNS.

The aggregation of a large number of people upon a limited area operates injuriously upon their health and lessens the mean duration of their lives. Many years ago Dr.—now Sir William—Gairdner of Glasgow pointed out that whilst the death-rate in England was 15 per 1000 persons living on every square mile it rose as the density of population increased until it became 27 and upwards when the population came to be 2900 per square mile. The death-rates in purely rural districts have not been very largely reduced since the beginning of the present century; in the towns the case has been different. Before the system of national registration of deaths was adopted there existed the means of closely approximating the death-rates in towns. From the "Bills of Mortality" of London we learn that the death-rate in that city during the period 1728 to 1780 was about 50 per 1000 persons living. The deaths therefore greatly exceeded the births, and were it not for the great immigration into the city from the country its population would have become extinct, as the mean age at death of the citizens was only 20 years. According to Sir William Petty, the deaths in London in six years of the seventeenth century exceeded the births by about five-eighths. He showed that at the same period the same relative proportions between births and deaths existed in Dublin.

For centuries the urban death-rates greatly exceeded the rural rates, in many cases by from 20 to 50 per cent.; but during the last 40 years they have been approximating, although a gap far too wide still divides them. In 1896 the estimated population of England and Wales amounted to 30,717,355, of whom 14,883,806 resided in 110 town-districts, each containing more than 35,000 inhabitants, and 15,833,549 in country districts and towns and villages having a smaller population than 35,000. The death-rate in the urban districts was 18 and in the rural districts 15·3 per 1000, the difference being 2·7 per 1000. The mean rates in the previous 10 years were 19·7 and 17·2, a difference of 2·5. Let us compare these figures with the statistics of the decade ended in 1860; in that period the urban rate was 24·7 and the rural 19·9, the difference being 4·8. Gratifying as it is to find the gulf between the urban and country death-rates narrowing, it is unsatisfactory to observe that the rate of mortality should be so much greater in some towns than in others. In 1897 the rate in Eastbourne was 8·2, in Bournemouth 10·1, in Croydon 13·62, and even in the manufacturing town of Darlington 15, whilst in Liverpool it was 26·76 and in Salford 26·88. Brighton, a most fashionable town with a well-to-do population, had a death-rate of 15·23; but Wakefield, Stockton-on-Tees, and Jarrow — all manufacturing towns—had almost the same rate.

CAUSES OF THE HIGH URBAN DEATH-RATES.

The causes which raise the urban death-rates so much above the rural ones are numerous and perhaps not fully discovered. The causes of the enormous difference between the bills of mortality of the healthiest and least healthy of the towns have not been fully investigated. The contagion of the fevers must clearly be more readily conveyed from the sick to the sound in towns owing to the closer contact of the people. The town atmosphere is less pure than the air of the country; its soils are generally contaminated with filth. In its narrow streets and courts the direct sunlight—so necessary to maintain the purity of the air—and thorough ventilation are wanting. The effete matter from dwellings and workshops and the sweepings of the streets are sometimes allowed to accumulate and to pollute the air by their noisome exhalations. Many of the occupations of townspeople are of a more or less unhealthy nature and the majority of them are sedentary. The outdoor life of the farmer and agricultural labourer is obviously more healthy than that of the town bakers, shoemakers, tailors, mill-workers, &c. The cabin of the peasant may be, and indeed too often is, a wretched dwelling, but it is at least surrounded by the pure and open atmosphere. In the towns a dozen families often occupy as many rooms in the same house, whilst hundreds of similar houses invest it on all sides. In the narrow back street and close court we see the children of the poor with bleared eyes, colourless lips, and pallid faces, pining for fresh air and a view of the wide canopy of the sky. How different is not the lot of the country child and young person. They see the hills resplendent with the sheen of the golden gorse, they inspire air fragrant with the perfume of the hawthorn and of many a sweetly odorous flower, they roam over fields of emerald green, through shady woods and by purling brooks and silver rivers, whilst the air is filled with the melody of the feathered warblers. With such environments the country child develops into a strong and healthy adult. We can hardly expect to make the conditions of infantile life so healthful in town as they are in the country, but much can be done to brighten the life of the children of our great towns, to give a roseate tinge to their pale cheeks, and to strengthen and develop their muscles. Their dwellings should be improved, and places for their recreation in the open air liberally provided. The Earl of Meath has generously established in Dublin two gymnasia and playgrounds for children and the corporation are providing a gymnasium on the open space formed by the removal of an old prison in Green-street. Gymnasia for children are, however, required in all parts of this city and of other cities. As the child is in one sense the father of the man every effort should be made in favour of the physical,

moral, and intellectual culture of those who are to form the future men and women of the nation.

THE SANITARY CONDITION OF TOWNS IMPROVING.

The appalling high death-rates in towns which continued for many centuries have greatly decreased in the present one. The improvement is partly due to greater attention to personal hygiene and a higher standard of comfort, partly and chiefly to improved public sanitation. The "masses" are now, on the whole, better fed than they were formerly, their hours of labour are less, and they enjoy more holidays. The causes which rendered so many of the handicrafts unhealthy and even dangerous have been removed or their effects lessened. Before the second half of the present century the Public Health Acts enacted were few in number and, as a rule, were not mandatory on the local authorities. The English Public Health Act of 1872, amended in 1875, and the Irish Public Health Act of 1875, amended in 1878, were the most comprehensive and valuable sanitary laws ever put upon the statute-books of these realms, largely owing to the compulsory nature of many of their sections. Under the provisions of these and several subsequent Acts a great improvement has been effected in nearly all the large towns of these countries. During the ten years ended in 1850 the mean annual death-rate in London was 24·8 per 1000 persons living; in the decade ended in 1896 the rate was 19·9 or 4·9 per 1000 less than in the former period. In 1897 the rate was only 17·7, excluding the deaths of strangers in London. In Glasgow, where vast sums have been expended in the clearing of unhealthy areas and the erection of improved dwellings for the working classes, a great decrease has taken place in the general and zymotic death-rates. In the ten years ended in 1866 the deaths from all causes were in the ratio of 30·2 per 1000 of the population; in the five years ended in 1897 the rate was only 21·8. The death-rate in Liverpool in the years 1866 to 1875 was 31·3 per 1000; in the years 1887 to 1896 it was 25·7 and in 1897 24·4. The Manchester death-rate was 31 in 1866–1875; in 1887–1896, 25·3; and in 1897, 23·1. Similar statistics could be quoted in reference to almost every other large town.

THE INCREASE IN THE ENGLISH URBAN POPULATION HAS NOT CAUSED AN INCREASED DEATH-RATE.

In all parts of the world the mean duration of human life is decidedly less in the towns than in the country. In comparing the vital and mortal statistics of countries the relative proportion of their urban and rural populations is a factor of considerable importance. If in one country only 1 in every 10 of the inhabitants lives in a town, and in another country 1 in 5, then, *cæteris paribus*, a lower death-rate might naturally be expected as regards the former country. In England by far the larger proportion of the people are located in the towns. In the middle of May of the present year the population of the urban registration districts numbered 21½ millions out of a population of 31,397,078. What a contrast does not this enormous town population present to that of other countries, say to Russia? Of the population of that empire, which numbered last year 126,411,736, only 16,289,184 resided in the towns, some of which were indeed mere villages. Only 8 of the towns had a population exceeding 180,000 each. Notwithstanding the fact that an increase in the density of a population is unfavourable to health, the rapid increase in the English urban population has not sensibly counteracted the good effects produced by improved public and private hygiene. The density of the population of London has been doubled since 1851. It is truly wonderful that its vast population of 6,291,667, located on only 693 square miles, should have in 1897 so low a death-rate as 17·7 per 1000. This rate is not greater than that of a fairly healthy rural district. England well deserves the name she has received as the birthplace and home of sanitary science and practice. That the health of the English people continues to improve the following statistics prove:—

Mean Annual Death-rate in England and Wales.

1847–1850, 23·2; 1851–1860, 22·2; 1861–1870, 22·5; 1871–1880, 21·4; 1881–1890, 19·1; 1891–1896, 18·45.

The reduction in the death-rate has been chiefly effected by the improved state of the public health in towns.

Mean Annual Death-rate in the Towns.

1851–1860, 24·7; 1861–1870, 24·8; 1871–1880, 23·1; 1881–1890, 20·3; 1891–1896, 19·24; 1897, 16·84.

In the period 1851–1870 the deaths in the towns were 25 per cent. greater than the deaths in the country for equal numbers of the people; in the period 1871–1896 the excess was reduced to 13·5 per cent., or nearly one-half. *En passant* I may here remark that the death-rate is much lower amongst females than males. It may interest intending benedicts and strengthen their resolution to learn that the mean duration of life is greater amongst married men than is the case with celibates. No doubt the former are taken better care of. Attention has been called to the decided decline in the birth-rate not only in the United Kingdom but in most European countries; but it seems clear that such a decline must necessarily follow a diminished rate of mortality resulting in an increase of the numbers of the population upon which the birth-rate is calculated. The lowest birth-rates ever registered in England were in 1894 and 1896 and in these years the lowest death-rates were also recorded.

MORTAL STATISTICS OF IRELAND.

The death-rate in Ireland is for the whole country very low. In the ten years ended in 1896 it was only 18. In the same period the rate in Hungary was 35·6 and in Austria 30. The low rate in Ireland is largely due to the circumstance that by far the larger portion of the population reside in the open country. The urban bills of mortality are very high. In the decade ended in 1897 the death-rate was 24·65 per 1000 in the 23 largest towns. Their zymotic death-rate was 2·64. There is therefore a great difference between town and country death-rates in Ireland.

STATE OF PUBLIC HEALTH IN DUBLIN.

As this Congress is meeting in Dublin it seems fitting that some account of the sanitary state of the city should be given to it. Thirty-two years ago the sanitary staff of Dublin consisted of one whole man (an inspector of nuisances) and a small part of another man (the secretary to the Markets Committee). At present the staff consists of a superintendent medical officer of health, who holds also the position of public analyst and executive sanitary officer; 15 district medical officers of health, who hold that position *ex officio* as Poor-law medical officers; a sanitary engineer; a superintendent and assistant-superintendent of sanitary sub-officers—i.e., nuisance inspectors; 23 sanitary sub-officers; 3 inspectors of dairies; 3 food inspectors; an inspector of slaughter-houses; 2 inspectors (one a lady) under the provisions of the Shop Hours Act and about a dozen persons, exclusive of whitewashers and charwomen, engaged in disinfection operations and the removal of fever patients to hospital. The disinfecting premises have recently been improved and enlarged at a cost of £2000, and a large isolated house, the property of the corporation, has been fitted up at a cost of £500 as a refuge for persons whose dwellings are undergoing disinfection. Since 1895 no person has been appointed a sanitary inspector unless he proved his fitness for that position by a competitive examination. Sixteen of the sanitary inspectors hold certificates of competency granted to them after examination by the Royal Institute of Public Health. The estimated expense of the sanitary department, exclusive of the cost of making and maintaining sewers, was in 1897 £23,607. Salaries and wages amounted to £9068 10*s*. £1040 were, however, received as a Parliamentary grant in aid of the salaries of the sanitary officers and a considerable revenue is derived from the baths and washhouses and other sources.

Loans for the following purposes have been sanctioned and all but a small portion obtained and expended: for clearing unhealthy areas (on which the Dublin Artisans' Dwellings Company have since erected houses), £54,200; artisans' and labourers' dwellings, £137,323; new streets, by which slums were cleared away, £116,000; public abattoir, £16,700; baths and washhouses, £12,500; improvement in disinfection house, £2000; a refuge for persons whose houses are being disinfected, £500; a mortuary, £200; open spaces, £2900; offices for sanitary department and city laboratory, £10,000; underground sanitary accommodation, £2200 = £354,523. For the following purposes, which also tend to improve the public health, loans have been sanctioned and nearly altogether obtained: sewers and works connected with them, £62,107; works in connexion with public and domestic scavenging, £34,050; paving, flagging, and concreting, £421,988; fish and vegetable markets, £98,800; "private improvement"

Digitized by Google

expenses, £12,628. All these make a total of £984,096. For another great sanitary improvement—namely, the main drainage of the city—a loan of £350,000 has been sanctioned and is being expended. Lastly, if we add the cost of the improved supply of water to the city—namely, £720,000—we have a grand total of £2,054,096 expended on purposes all of which tend to improve the health and comfort of the citizens. When the main drainage and sewage precipitation scheme is completed—probably in about two years more—the Liffey will no longer be polluted and the sewage, now impounded for many hours daily, will flow uninterruptedly through the sewers.

I hardly venture to claim that the large sum of money expended in sanitary works in Dublin and the exertions of the sanitary department of the Corporation have been the chief means by which the reductions in the death-rate have been effected. I have, however, no doubt that if the sanitary staff still consisted of only one individual and part of another there would be much more fever in Dublin than there has been for some years past. In the five years 1876–1880 the death-rate was 29·5; in the period 1881–1885 27·4; in the next five years 26·8; in 1891–1895 26·1; and in 1896–97 26·3. In 1897 the death-rate was raised by epidemics of measles, whooping-cough, and scarlet fever. In the ten years ended in 1885 the mean zymotic death-rate was 4·1; in the following ten years it fell to 2·62, or 44 per cent. In 1896 the rate was 2·4, but in 1897 it rose to 4·5 in consequence of an epidemic of measles and slight epidemics of whooping-cough and scarlet fever. Notwithstanding these epidemics, and one of small-pox in 1894–1895, the zymotic death-rate for the five years ended in 1897 was slightly below that of the English towns. The figures are as follows: 33 largest towns, 2·84; London, 2·82; Dublin, 2·80. In the first half of the present year the rate was 1·7 in Dublin.

I have given these figures in proof that Dublin is not the hotbed of fevers which even some of its own citizens believe it to be. The visitors at this Congress may rest assured that they are not more exposed to contagion than they would be in London or Manchester.

Peculiarities of the Dublin Death-rate.

If we considered only the zymotic death-rate and the infant mortality of Dublin, the sanitary condition of the city would appear to be as satisfactory as that of the English towns and even as that of London. Many sanitarians regard the infant death-rate to be as a measure of the salubrity of a district almost equal to that afforded by its fever mortality. In the following table I give the death-rate of infants under one year of age in the 10 years ended in 1897 in Dublin, London, and the 33 large English towns:—

Deaths of Children under One Year of Age in the Five Years ended in 1897.

—	Rate per 1000 of the estimated population under one year of age.	Rate per 1000 of the registered births.	Proportion per 1000 of the total deaths.	Rate per 1000 of the total population.
England and Wales	152·6	152·2	254·8	4·58
33 Largest English towns...	174·6	171·8	272·0	5·36
London	158·2	159·6	252·4	4·82
Dublin	171·0	169·8	166·4	3·92

In all Ireland the deaths of children under one year of age are, as a mean, about 99 per 1000 registered births. These figures prove that no larger proportion of the infants born in Dublin perish in the first year of their existence than is the case in the 33 largest English and Welsh towns. The small percentage of total deaths, which are those of infants, as compared with the English towns indicates a very high rate of mortality amongst those of greater age. Whilst the infantile mortality is less in Dublin than it is in the 33 largest English and Welsh towns, it is practically the same as that of the 67 smaller towns (with an aggregate population of 3,812,631)—namely, 169. In some of these towns the infantile death-rate was very high—in Wolverhampton it was 217; in Salford, 219; in Ashton-under-Lyne, 228; in Langton, 252; and in Preston, 262. The high infantile mortality is chiefly due to neglect and the physical evils arising out of poverty. Amongst the well-to-do classes about 6 per cent. of their deaths are those of children under five years of age, whilst out of every 100 deaths of persons belonging to the labouring classes 40 are those of children under five years of age.

The children of the poor suffer from the insufficiency and improper nature of their food. They are not adequately protected from cold in winter. It is melancholy to see tender boys and girls out in the streets in the depth of winter shoeless and with only the most scanty garments. Young persons offer less resistance to the influence of cold and wet than adults; yet even sometimes amongst the rich we see the naked legs and arms of young children exposed to a temperature which would make their parents shiver if they were not well protected by warm clothing. The Society for the Prevention of Cruelty to Children and the Police-Aided Society for providing clothing for poor children are associations which deserve the warmest sympathy and generous support of the humane public. They have done great good and could do much more if they were adequately supported. Deserving, too, of a great tribute of praise are the kind people who provide a day's "outing" in the country for the children of the slums and those, too, who secure for the pale seamstress and the tired shop or factory girl a few days in the country. The change may be all too brief, but it at least more than realises the earnest wish of the poor toiler expressed in one of Hood's most pathetic poems:—

> Oh, but to breathe the breath
> Of the cowslip and primrose sweet,
> With the sky above my head,
> And the grass beneath my feet,
> For one short hour.

Why is there a High Rate of Mortality in the Adult Population of Dublin?

Amongst the poorer classes there is in every town a higher death-rate than prevails amongst the affluent classes. I have long been of opinion that as compared with London especially, and with many other towns, there is a larger proportion of the poorest classes in Dublin. It is admitted that Ireland is a very much poorer country than either England or Scotland. It is highly probable that this comparison holds good for town as well as country. If that be the case we may to some extent account for the high mortality from non-infective diseases in Dublin, as compared with the English towns, from the circumstances of the larger number of poor people in the former. Dublin and London cannot be fairly compared, for, as Dr. G. V. Poore truly remarks,[1] "London is very largely a city of wealthy and well-to-do people, most of whom must be looked upon as sojourners rather than dwellers in the city. Amongst such as these, who command every luxury and necessary in life, including change of air, death-rates ought to be low." Mr. Sergeant, in a paper published in the *Journal of the London Statistical Society* for June, 1864, advances the opinion that in comparing the death-rates of London and Birmingham an allowance of 1·5 per 1000 should be made in favour of the latter on account of the comparatively small proportion of the affluent classes which inhabit it. To our distinguished Registrar-General, Dr. Grimshaw, is due the merit of being the first to publish the rates of mortality amongst the different classes of the Dublin community. When similar information is given in the reports of the English and Scotch Registrars-General we shall then be in a position to form some estimate of the relative proportions of the poorer classes in Dublin as compared with London, Edinburgh, and other cities.

Housing of the Very Poor.

The improvement in the viability of the working classes which has taken place within the last 30 years is to some extent due to the better dwellings provided for them. Owing to the benevolence of the late Mr. Peabody, Lord Iveagh, and other philanthropists a considerable number of healthful dwellings have been built for artisans and labourers. A still larger number have been erected by companies, some of which have been founded on semi-philanthropic, semi-commercial lines. In this city and its suburbs the Dublin Artisans' Dwellings Company own dwellings occupied by 2194 families, who pay from 1*s.* 9*d.* to 12*s.* per week. This company is now constructing 188 additional dwellings. The City and Suburban Artisans' Dwellings Company have provided dwellings for 284 families, who pay

[1] Dr. G. V. Poore: London, Ancient and Modern, From the Sanitary and Medical Point of View.

Digitized by Google

from 2s. 6d. to 6s. per week; the Industrial Tenement Company own a block of buildings in which there are 46 separate tenements let at from 2s. to 4s. per week. Many employers of labour, such as railway companies, brewers, distillers, &c., have erected improved dwellings for their employés. Fourteen years ago I suggested to the corporation the desirability of putting in force the provisions of the Housing of the Working Classes Acts. The suggestion was acted upon and at the present time the corporation have provided 375 separate dwellings, let at the following rents—25 from 6s. 6d. to 10s. (with shops), 12 from 4s. 9d. to 5s. 6d., 84 at 4s. 6d., 98 from 3s. 6d. to 4s., 98 from 2s. 6d. to 3s. 3d., 47 at 2s., 14 at 1s. 9d., and 23 at 1s. 6d. Although so much has been done in providing improved dwellings for the working classes the vast majority of them are still lodged in wretched tenements. A few years ago I had a kind of census taken of the city and found that 32,000 families were located in about 7000 houses, affording 1½ rooms per family. On the other hand, the remaining 22,000 families of the city occupied 17,000 houses.

Whilst much has been accomplished in the way of providing proper dwellings for artisans and the better class of unskilled workers, practically nothing has been done to improve the miserable state of the homes of the very poor. In every large town there are, exclusive of beggars, thieves, and vagrants, &c., many honest people whose precarious earnings barely suffice to keep body and soul together. Amongst this class are to be found small dealers, pedlars, hawkers, charwomen, rag-pickers, night-watchmen, the inferior class of seamstresses, porters, and labourers, the miserable creatures carrying placards termed "sandwichmen," and men and women engaged in many other poorly remunerative employments. Besides these there are the dull-witted and the physically feeble people who are only capable of earning the merest pittance. It is in the wretched homes of the poorest of these poor that the seeds of fever are developed as in a hotbed. Their dwellings are a peril to the whole community, for their inmates carry contagious matter into the streets, shops, factories, and other places. The effluvia from them taint the atmosphere, in the purity of which all are interested. It is the dwellings of the very poor which demand nearly all the attention of the sanitary inspector. He finds it almost an impossibility to get their owners—who are often nearly as poor as their tenants—to keep them in even moderately good condition.

Since 1879 more than 3000 houses have been de-tenanted and closed in Dublin on account of their insanitary condition; of these not one-half have been rebuilt or rendered fit for human occupation. The closing of insanitary houses and the clearing of unhealthy areas have, however, been of little benefit to the poorest of the poor. The people who live on the unhealthy areas have not returned to occupy the neat dwellings which replaced their wretched tenements. The rents of the new dwellings were beyond their means. The unhealthy areas have been cleared, but the condition of the people who dwelt on them has remained unchanged. They have sought on other areas low-rented tenements as insanitary as those from which they had been ejected. If all the lowest rented and consequently least sanitary of the Dublin tenement houses were compulsorily closed, where, save in the workhouse, could their inmates obtain shelter? I feel convinced that the ordinary landlords of tenement houses, the majority of whom are leaseholders only or yearly tenants, cannot provide proper dwellings at from 1s. to 2s. per week, the rent which the very poor can only afford. Dwellings so low-rented can only be provided by the municipality or by philanthropic societies and individuals. They will pay very little if any interest on the money expended on their erection and maintenance, but every unhealthy dwelling which they replace will be a distinct gain to the whole community. The replacement of unhealthy by healthy habitations means less illness, longer duration of life, and diminished pauperism. It may be said that if you give a dwelling to a man at less than its market value you pauperise him. To this it may be rejoined that children are not pauperised by receiving their education free; the students in the State-endowed colleges and universities are not pauperised by acquiring, not merely a general education, but money making professions chiefly at the cost of the taxpayers. We already give the poor medical advice and medicine gratis; let us go a step further and provide the most dependent of them with dwellings in which they can live under reasonably healthy conditions. An attempt is now being made to raise a sum of money sufficient to erect a block of tenements which it is proposed to let at from 1s. 6d. to 2s. a week. It is to be hoped that generous support will be given to those who are engaged in this meritorious project.

THE MUNICIPAL AUTHORITIES SHOULD BE ENCOURAGED TO PROVIDE WORKPEOPLE'S DWELLINGS.

The borrowing powers of municipal authorities are limited to a sum equivalent to two years' valuation of the town for rateable purposes. Thus, if a town were valued at a million pounds its governing body would be empowered to borrow two millions. When this restriction was placed upon civic authorities the money borrowed by them was expended nearly if not altogether on what might be termed unproductive works, such as the paving, sewering, and lighting of the thoroughfares, &c. It seems to me to be unreasonable that the money expended by urban authorities in providing artisans' dwellings, baths and washhouses, abattoirs and markets, from which revenues are derived, should be included in the amount authorised to be borrowed. Mortgages on these buildings as well as the security of the rates is required by the Treasury for loans granted in connexion with them. It is evident that as the loans for the erection of artisans' dwellings are to be placed in the same category as loans for sewers and other non-revenue producing works the power of municipal authorities to provide dwellings for the working classes must be extremely limited. It is to be hoped that this disability will soon be removed. The market value of the artisans' dwellings in the possession of the sanitary authorities should be ascertained and the sum found added to the amount allowed to be borrowed on the two years' rateable valuation system. Thus, if a corporation could borrow a million for unproductive purposes and that it possessed artisans' dwellings valued at £100,000, then their borrowing powers should be extended to £1,000,000.

RACK-RENT IN RELATION TO PRIVATE IMPROVEMENT EXPENSES.

In the abatement of nuisances involving structural alterations in a dwelling the expense has frequently to be defrayed by persons having little or no interest in the benefits derived from the structural alterations. In order to prevent this injustice, as it may be termed, an amendment of the Public Health Acts of both England and Ireland is necessary. The cost of private sanitary improvements insisted on by the sanitary authority is borne by the person who receives the rack-rent of the premises. The definition of rack-rent in the English Public Health Act of 1875 is not so simple as that in the Irish Act, which defines it to be two-thirds of the rateable valuation of the premises. Thus, if a landlord lets a house for £60 a year which is valued at £40 he receives a rack-rent and must pay for the cost of sanitary improvements, although he may have let the premises on lease for 999 years. In such a case as this surely it is the leaseholder who ought to pay for the improvements, as he alone enjoys them.

A curious point in connexion with private improvement expenses is the liability of the person who receives rent from the occupier for the cost of the improvements although he himself may pay a rack-rent. He is termed the "immediate" rack-renter. I know of a case where a person who paid £80 a year for a house valued at £75 was obliged to sub-let it for £60 in consequence of depreciation of house property in the street. Although losing £20 a year by the house he was obliged to pay nearly £50 in providing it with improved drainage and sanitary arrangements, whilst the landlord, who received £80, was by law exempt from contributing to the expense of the improvements. It seems only fair that every person having a beneficiary interest—present, proximate, or remote—in a house should be obliged to contribute to the expense of its improved sanitation, the proportion to be determined by the magistrate who makes the order for carrying out the improvement.

THE WATER-CARRIAGE OF FILTH.

When, in 1879, the Department of Public Health was placed under my direction I commenced to wage a determined war against the system of storing filth in pits which had prevailed in Dublin for centuries, exclusively in the poorer quarters of the city and partially in the other districts. To this storage of filth must be ascribed the polluted condition of the soil which still has not yet been got rid of. It was no

Digitized by Google

easy task to induce or compel the owners of houses to adopt the water-carriage system of filth removal, but the task has practically been accomplished. Unfortunately the occupants of the tenement houses too often do not take proper care of the improved sanitary conveniences supplied for their use and the landlords complain that they are constantly called upon to repair injuries to the sanitary arrangements due to the action or carelessness of their tenants. The Public Health (Ireland) Act provides that in the case of two or more houses having sanitary accommodation in common the tenants can be collectively proceeded against for the abuse of the sanitary arrangements. The law should be made to apply to single houses inhabited by two or more families. In this connexion I would like to express my strong opinion that every separate dwelling should be supplied with sanitary arrangements for its exclusive use. Those which are used in common by several families will never be kept in proper order. I may mention that in the corporation artisans' dwellings, Bow-lane, every tenement—and there are 24 let at only 2*s.* a week—has its own scullery and sanitary arrangements.

There are many persons, including medical men, who believe that the general introductiou of the water-carriage system of filth removal has not been a benefit to Dublin but the reverse. They are under the inpression that fever has increased since the old system of filth storage has been superseded. The statistics which I have brought before this Congress conclusively disprove the statement that fever has increased in Dublin; it has, on the contrary, decreased. In every town in the United Kingdom in which the water-carriage system has been adopted the public health has been improved. Dr. Scurfield, medical officer of health of Sunderland, shows in a report presented to the corporation of that town in 1897 that in 33 towns in which the water-carriage system of filth riddance prevails the deaths from enteric fever averaged 15 per 100,000 of the population; while in 33 towns in which the conservancy method remained the rate was 26 per 100,000. In the former the deaths from diarrhœa were in the ratio of 52 per 100,000, whilst in the latter the rate was 108. The deaths from all causes were 2·6 per 1000 more in the conservancy, than in the water-carriage towns. In Nottingham during the period 1887–1896 there was 1 case of enteric fever in every 558 houses from which filth was removed by the agency of water, whilst in every 37 houses having middens there was 1 case of this fever. At the International Hygienic Congress held in Madrid this year the following resolution was adopted: "That the general health of the population is improved and the spread of the disease prevented in towns and dwellings by the immediate removal of all foul matters and by a copious supply of pure water."

PREVALENCE OF TYPHOID FEVER IN DUBLIN.

The mortality caused by typhoid fever is greater in Dublin than in nearly every other town in the United Kingdom. In Ireland Belfast alone has a higher death-rate from this disease. On the other hand, diphtheria is very much less fatal in Dublin than in the English towns. I have come to the conclusion that both diseases have, to a great extent, a telluric origin; they seem to be in some way intimately connected with the soil. If, then, we take both and regard them as semi-malarial, Dublin will not occupy a worse position than the English towns. The deaths from enteric fever and diphtheria combined were in 1887–1896 in the ratio of 55 per 100,000 persons living in Dublin and 60 per 100,000 in London. In 1897 the rate was 54 in Dublin and 64 in London. In 1896 the mean diphtheria rate alone was 50 per 100,000 in London, Wales, Essex, Kent, and Worcestershire; in Dublin diphtheria and enteric fever combined caused 44 deaths per 100,000 inhabitants. Dublin has a supply of water of great purity; its street sewers can compare favourably with those of other towns; and the plumbers' work in its houses is as good as it is in the great majority of towns. Why, then, should there be so much enteric fever in Dublin? I have long been of opinion that the micro-organisms of this disease have an abiding place in its soils, which for so long a period were polluted by leakage from the filth receptacles and defective sewers of former times. I believe that, under certain conditions to which I have often referred in papers and reports, these malignant organisms escape from the soil into the atmosphere, from which they pass through various media into the bodies of human beings.

That there is a connexion between enteric fever and the soil is shown by the results of observations of the distribution of more than 4000 cases of the disease in Dublin. Where gravel forms the site of streets there is far more typhoid fever than in districts which rest upon the stiff boulder clay. This is clearly owing to the fact that the bacillus typhosus, which is aerobic—that is, requires oxygen—can get it more freely in the loose gravels than in the stiff clays. In the gravel, too, there is a much greater space for the development and movement of the bacilli. It has long been assumed that the soil of Dublin lying nearest to the river was always water-logged, and it was suggested that the drainage of this soil and its subsoil might lessen the prevalence of enteric fever. A few years ago I caused a number of wells to be sunk in the ground near the river and at the higher parts of the city. Long-continued observations of the height of the ground or subsoil water in those wells proved that in the higher parts the water came to within 4 or 5 feet of the surface of the ground, whilst near the river the water remained at from 12 to 18 feet from the surface. It seems strange that the surface of that part of the city from 50 to 70 feet above the level of the river at high water should be only 4 or 5 feet above that continuous sheet of subterranean water termed subsoil or ground water, whilst the low-lying districts have from 12 to 10 feet of dry soil. The explanation is, after all, a simple one. The low-lying districts rest on gravel, which permits the rain to sink into it very deeply, whilst the high grounds are stiff clays which retain the water. When a soil becomes infected by the *materies morbi* of typhoid fever it is difficult to eradicate it. The recent experiments of Dr. Sidney Martin, recorded in the supplement to the annual report of the English Local Government Board for 1896–97, show that typhoid bacilli put into soil multiply in it and ramify throughout it; at the expiration of 105 days they were quite lively. These experiments and the investigations of other scientists, especially those of Dr. Robertson, clearly prove that typhoid bacilli can live and multiply in soils containing organic matter. I feel satisfied that they are to be found in the soils of Dublin and other places. Now that the pollution of the soil in Dublin has almost ceased we may expect that the *pabulum* of the typhoid organism will gradually be used up, with consequent diminution of the amount of enteric fever.

OUR DAYS BETTER THAN THE OLD TIMES.

The belief that former ages were happier than the one we live in does not rest upon a foundation of fact. The "brave days of old" of the poet were too often days of pestilence and famine, of war and rapine, of might over right, of coarseness of language, of absence of public opinion as a censor of morals, and of sanguinary criminal laws. During many centuries Europe was periodically devastated by pestilences. In the fourteenth century the terrible "black death" carried off 25,000,000 of its inhabitants. Population stagnated; that of England remained stationary for three centuries, not so much owing to war as to pestilence and famine. In 1664–65 the plague almost depopulated London. In that long and gloomy period, so truly named the "dark ages," the towns were the hotbeds of disease from which their poisonous seeds were spread throughout the land. Their denizens were crowded into ill-ventilated houses in narrow, sunless streets. Their water-supplies were polluted by the oozings from cesspools which were almost as numerous as the houses themselves. There were no main sewers, no systematic removal of filth, no municipal sanitary organisations. Even as late as the last century Howard the philanthropist drew terrible pictures of the insanitary state of the prisons and even of many of the hospitals and orphanages. The wretched condition of the floating homes of sailors, even those of the Royal Navy, is graphically described in the humorous but truthful pages of Smollett. The present time is better than the old time. Leprosy and malarial fevers have vanished from these countries. Typhus fever, which once filled the wards of the Dublin Fever Hospital with patients, is now rarely met with. Fifty years ago people disfigured by small-pox might be seen in every street; now that loathsome disease is disappearing under the influence of vaccination and the improved hygienic conditions of towns and people. In this connexion I must express my satisfaction that vaccination is still compulsory in Ireland, although no longer so in England. I believe that the medical profession are practically unanimous in regretting that the Vaccination Act just passed permits in England and Wales the so-called "conscientious objector" to refuse to have his

Digitized by Google

child vaccinated. In Ireland, if vaccination is sometimes neglected it is not from want of belief in its efficacy or contempt of the law—indeed, the complete absence of agitation in Ireland against compulsory vaccination is a proof of that respect for law and order so characteristic of the Irish people.

SANITARY EFFORTS SHOULD NOT BE RELAXED.

Although a great improvement has taken place in the state of public health in these countries and in most parts of Europe a further improvement is required and is attainable. So long as two or three out of every thousand of the population perish annually from diseases which are termed "preventable" so long must the efforts of the sanitary reformers and professors of preventive medicine be continued. Phthisis, which is as fatal as the "preventable diseases," ought now to be included amongst the latter, for its nature shows that it, too, might be eradicated. We require, perhaps, some additions to and amendments of our sanitary laws, but what is most required is the thorough enforcement of the laws such as they are—and they confer great powers upon the sanitary authorities. The notification of infective diseases and the laws relating to disinfection should be strictly enforced. The proper isolation of fever patients should be provided for. The speedy and complete removal of filth from houses and towns should be secured. Healthy dwellings and cheap baths and washhouses for the most dependent classes of the community should be multiplied. The "unhealthy occupations" should be rendered innocuous, or at least less unhealthy. The injurious emanations from certain kinds of works should be prevented or reduced to a minimum. These are only some of the measures required in order to assimilate our towns as nearly as possible to that ideal City of Hygeia which Richardson has described.

The efforts of a sanitary authority to improve the state of public health cannot attain to a full measure of success unless supported by public opinion and private practice. One of the objects of such associations as the Royal Institute of Public Health and the Dublin Sanitary Association is to educate the general public on the important subjects of public and domestic sanitation. Just in proportion as the citizen is convinced that his health and longevity are favourably affected by the operation of the sanitary laws will he respect and observe them, even at personal inconvenience and some expense. Let us hope that the Sanitary Congress which this day commences its deliberations in this ancient city will be able to prove that it is in the power of the citizens of Dublin to make it one of the healthiest cities in the world.

ABSTRACT OF

An Address

ON

IRELAND: ITS CAPITAL AND SCENERY.

Delivered before the Section of Chemistry and Meteorology at the Congress of the Royal Institute of Public Health held in Dublin, August 18th to 23rd, 1898,

By JOHN WILLIAM MOORE, M.D. DUB., F.R.C.P. IREL.,

DIPLOMATE IN STATE MEDICINE AND EX-SCHOLAR OF TRINITY COLLEGE, DUBLIN; FELLOW OF THE ROYAL METEOROLOGICAL SOCIETY.

[DR. MOORE opened his presidential address to the Section with some words of welcome to the members, after which he proceeded to consider the climatology of Dublin.]

Dublin, the metropolis of Ireland, stands at the extreme western end of the beautiful Bay of Dublin, close to the mouth of the River Anna Liffey, along both north and south banks of which the city extends for a distance of some two miles. It is 292 miles in a direct line W.N.W. of London, 138 miles W. of Liverpool, and 69 miles W. of Holyhead, and is situated in latitude 53° 20′ N., longitude 6° 17′ W. It comprises an area within the municipal boundary of 3733 acres, containing in 1891 25,764 inhabited houses and a population of 245,001. The Dublin Registration District consists not only of the city proper but also of the populous suburban districts of Rathmines Donnybrook, Blackrock, Kingstown, Clontarf, Howth, Coolock, Drumcondra, Finglas, Glasnevin, and Palmerston. The population of this "Greater Dublin" was, in 1891, 349,594, and its extent is 24,693 statute acres. The origin of the city is lost in the mists of antiquity. The Greek geographer Ptolemy, writing A.D. 140 speaks of a small tribe, the Eblani, as having established themselves at Eblana ("Civitas Eblana"), which was probably the site of Dublin. The dark peat-stained waters of the Anna Liffey gave its present name to the Irish capital, for the Celtic *Duibhlinn* signifies the "black pool." Among the Irish-speaking population of the west of Ireland Dublin retains its ancient name of Ath-Cliath. or more fully Baily-ath-cliath, the Celtic *Baile-atha-cliath* meaning the "town of the ford of the hurdles." From this name the obvious inference is that a wickerwork causeway stretched across the Liffey and that in its vicinity the town sprang into existence. The site of Dublin was originally not only beside a pool of dark water (*Duibhlinn*) but in a swamp, for the prefix "Anna" in the name Anna Liffey signifies literally a watery place, a marsh or swamp, annagh (*eanach*) being derived from *ean*, water. It is this untoward circumstance, perhaps, which in modern times has gained for Dublin so evil a reputation for the endemic prevalence of typhoid fever and diarrhœal diseases.

From a hygienic standpoint the meteorological factors of greatest importance in determining the climate of a given town or place are: (1) mean temperature; (2) extremes of temperature; (3) rainfall; (4) rainy days; and (5) relative humidity. Of somewhat less importance are: (6) mean atmospheric pressure; (7) amount of cloud; and (8) direction and force of the wind.

Mean temperatures.—Dr. Alexander Buchan has calculated the mean monthly and annual temperature of the city of Dublin on a mean of 40 years, from January, 1856, to December, 1895. His results are as follows:—

January	= 41·1°	July	= 60·3°
February	= 42·0°	August	= 59·4°
March	= 43·3°	September	= 55·6°
April	= 47·3°	October	= 49·4°
May	= 52·3°	November	= 44·5°
June	= 57·5°	December	= 41·6°

Year = 49·5°

Extreme temperatures.—Since January, 1865, the extreme readings of the thermometer in Stevenson's stand recorded in Dublin have been 87·2° on July, 15th, 1876, and 13·3° on Dec. 14th, 1882—a range of 73·9°F. The average annual range of mean temperature is not quite 20°.

Rainfall.—In the "Rainfall Tables of the British Islands, 1866–1890," published by the authority of the Meteorological Council in 1897, the mean rainfall at Fitzwilliam-square, Dublin, is given for the 20 years 1871–1890 as follows:—

	Inches.		Inches.
January	= 2·09	July	= 2·63
February	= 2·22	August	= 2·91
March	= 1·97	September	= 2·23
April	= 2·16	October	= 3·18
May	= 1·89	November	= 2·70
June	= 1·98	December	= 2·35

Total for the year = 28·31 inches.

February, 1891, was the driest month on record in Dublin. There were only two rainy days during the whole month, and the rainfall was but ·042 inch. September, 1865, also, had only three rainy days with a rainfall of only ·056 inch. An inch of rain—equivalent to a downpour of 101 tons of water on every statute acre—seldom falls within twenty-four hours in Dublin. On Oct. 27th, 1880, however, the measurement was 2·736 inches; on Aug. 13th, 1874, also, 2·482 inches of rain were registered; and on May 28th, 1892, 2·056 inches were recorded.

Relative humidity.—By this term is meant the percentage of saturation of the atmosphere with aqueous vapour. The relative humidity of absolutely dry air is 0, that of saturated air, when dew is deposited or fog forms, is 100. In Dublin the mean relative humidity in the twenty years, 1871–1890, was 82·5 per cent.

Mean atmospheric pressure.—Dr. Alexander Buchan calculates the mean monthly and yearly atmospheric pressure, reduced to 32° and mean sea level, in the City of Dublin during the 40 years—1856 to 1895 inclusive—to be—

	Inches.		Inches.
January	= 29·870	July	= 29·931
February	= 29·923	August	= 29·903
March	= 29·885	September	= 29·919
April	= 29·914	October	= 29·867
May	= 29·956	November	= 29·876
June	= 29·981	December	= 29·887

Annual Mean = 29·909 inches.

Digitized by Google

The absolute extreme readings of the barometer at any time taken by me were—maximum, 31·020 inches on January 9th, 1896; minimum, 27·758 inches in December, 1886. These readings assuredly represent the extreme range of atmospheric pressure, reduced to sea-level in Dublin—namely, 3·262 inches.

Amount of Cloud.—This climatological element varied in the 20 years, 1871-1890, from 64·5 per cent. at 9 A.M. to 56·5 per cent. at 9 P.M., the mean being 60·5 per cent. February is the most cloudy month (67 per cent.), May is the least so (55 per cent.).

Direction of the wind.—As regards this element, 14,613 observations were made during the 20 years, 1871-1390, with this result—N., 870; N.E., 941; E., 1409; S.E., 1267; S., 1323; S,W., 2051; W., 4030; N.W., 1750; calm, 972.

During the twenty years gales were recorded on 413 occasions, thunderstorms on 176 days, snow or sleet on 408 days, and hail on 622 days. In common with the rest of the British Islands Dublin owes its mild, equable climate in great measure to the proximity of the North Atlantic Ocean and its surface current of warm water, usually called the Gulf Stream, because its head-springs arise in the Gulf of Mexico. This sets in a north-easterly direction, laving in its course the western shores of Europe, and carries even into the Arctic regions north of Scandinavia temperatures from 20° to 30° above those due to the latitude alone. Other obvious causes of the mildness of the climate are the prevalence of south-westerly and westerly winds and the fact that a few miles south of the city lies a range of mountains with summits varying in height from 1000 to more than 2500 ft., while the keen, dry, searching easterly winds of winter and spring are much softened in their passage across the Irish Sea, so that during their prevalence the thermometer occasionally stands some 5° or upwards higher in Dublin than it does at Holyhead, although this latter place is actually on the sea. It is true that the converse holds good during westerly and north-westerly winds when severe frost sometimes occurs in winter in Dublin, while the thermometer remains decidedly above the freezing point at Holyhead. Yet these latter winds are never so piercingly cold and parching as those from easterly points. Nor is it in winter merely that the Irish Sea confers a benefit upon Dublin. In calm, clear weather in summer time no sooner has the sun mounted high in the heavens than a cool, refreshing sea breeze sets in towards the land, so that consequently extreme or oppressive heat is rarely experienced. Indeed, an oppressive atmosphere happens only when a damp, warm south-west wind is blowing with a more or less clouded sky. Temperatures above 80° in the screen in Dublin nearly always coincide with winds off the land, from some point between south and west and a clear or only slightly clouded sky. Among climatic epiphenomena the infrequency of thunderstorms and the relative frequency of hail showers in Dublin are worthy of note. In winter fog and frost often prevail in the city when a northerly breeze is blowing along the coast accompanied with a higher temperature and perhaps showers of rain. Lastly, in summer, with a westerly wind, heavy showers fall at times in the valley of the Liffey while the neighbouring higher lands enjoy dry weather.

This may, perhaps, be a suitable occasion on which to direct attention to a much-needed reform in the keeping of time in Ireland. For many years the time-standard in this country has been so-called "railway-time," more strictly Dublin time, or rather the time of the meridian of Dunsink Observatory, co. Dublin. It is, however, a matter for consideration whether Greenwich time should not be adopted as the standard for Ireland as it already is for Great Britain. If an objection is raised that a national question is involved it is only necessary to point to Scotland and Wales, where the national sentiment runs as high as it does in Ireland and which have long since adopted Greenwich time. As a matter of fact, however, the question is that of West European time, which is applicable to a zone extending 7½ degrees of longitude both east and west of the Greenwich meridian. France has lately adopted this time, just as Switzerland and Germany have arranged to set their watches by Central European time, which extends from 7° 30′ E. long. to 22° 30′ E. long. For many years Greenwich time has been adopted in the Postal Department and Irish telegrams are despatched and received by it. As a matter of public convenience the principle should be extended, and so the existing confusion in time-tables and in telephonic communication between Great Britain and Ireland would cease. Let the secretaries of the various steamboat and railway companies agree upon so desirable a reform and the thing is done. It would, however, be necessary afterwards to amend the Statutes (Definition of Time) Act, 1880, which provides that whenever any expression of time occurs in any Act of Parliament or other legal instrument it shall be held in Great Britain to be Greenwich mean time and in the case of Ireland to be Dublin mean time.

[Dr. Moore here gave English renderings of many names of places near Dublin, acknowledging his indebtedness to the "Origin and History of Irish Names of Places," by P. W. Joyce, and concluded his address with an account of a ten days' tour which he made in the spring of the present year through the south and south-west of Ireland, from Waterford to Lahinch and Lisdoonvarna in county Clare.]

ELECTRO-MAGNETIC EXTRACTION OF FOREIGN BODIES FROM THE EYE.

BY J. JAMESON EVANS, M.B., C.M.EDIN., M.R.C.S.ENG.,
HONORARY SURGEON AND LATE RESIDENT SURGICAL OFFICER TO THE BIRMINGHAM AND MIDLAND EYE HOSPITAL.

THAT the electro-magnet is of value in ophthalmic surgery is fully established by the record of successful cases which have been published from time to time; but there is still a considerable amount of doubt and divergence of opinion as to its exact *rôle* as a strictly conservative agent. For example, Hirschberg gave his favourable results as 10 per cent., while Mayweg's were 31 per cent.; Knapp's results were even less favourable than those of Hirschberg. This is a point which can only be established by the record of series of cases preferably drawn from the practice of one individual or institution. As such, the following series, which represents the electro-magnetic extractions at the Birmingham and Midland Eye Hospital during a period of about two years, will, I think, prove of some value. I have also endeavoured to present some of the dangers and complications, both immediate and remote, of electro-magnetic extractions. The later records of some of the cases are unfortunately incomplete owing to the fact that the patients have failed to report themselves. During a corresponding period there were 16 cases in which the electro-magnet was introduced into the eye, but no foreign body was found. These I shall not detail in full, but I will give a short analysis of the results. I would mention that the instrument used was that of Snell and the current was supplied from a secondary battery. Strict antiseptic precautions were observed in every case.

I will give first a short account of the cases in which the eye had to be excised or eviscerated. Of these there are 4, 2 only being due to suppuration.

A.—FOUR CASES IN WHICH THE EYE WAS LOST.

CASE 1.—A patient, aged eighteen years, was admitted to hospital on May 30th, 1896, having been "struck in the right eye by a piece of steel" on the day of admission. The foreign body (a piece of steel) was floating in the vitreous and was visible with and without the ophthalmoscope when the pupil was dilated. The wound of entrance was through the sclerotic about ¼ in. behind the corneal margin on the outer side. A large piece of steel, measuring about ¼ in. by ⅛ in., was removed by the electro-magnet from the lower part of the vitreous, the scleral wound being enlarged for its extraction. The foreign body was easily removed by one insertion of the magnet and with the least amount of disturbance of the vitreous. The eye at the time was perfectly quiet, the wound in the sclera and a slight hæmorrhage into the lower part of the vitreous being the only signs of damage to the eye. On June 2nd the eye showed signs of infection, there being conjunctival and ciliary congestion, haze of the vitreous, chemosis, and œdema of the lids. The suppuration progressed in spite of treatment and on the 8th the eye was eviscerated.

CASE 2.—A patient, aged nineteen years, was admitted to hospital on June 30th, 1896, with a perforating wound of the left cornea and traumatic cataract. There was a foreign body in the vitreous just behind the iris. The foreign body

Digitized by Google

was removed by the electro-magnet on the day of admission. A small iridectomy was performed. On July 1st the anterior chamber was reformed; there was some muco-purulent discharge. On the 3rd there was congestion of the eye with discolouration of the iris. Haze of the media and suppuration set in and on the 8th the eye was eviscerated.

CASE 3.—A patient, aged fifteen years, was admitted to hospital on July 12th, 1897, with a perforating wound of the right lid and sclera. There was hyphæma. A foreign body was in the globe (?). The vision of the right eye equalled perception of light; there was no projection. On the 14th a large piece of steel was extracted by the electro-magnet. Recurrent hæmorrhages into the eyeball followed and the eye was excised on August 6th.

CASE 4.—A patient, aged twenty years, was admitted to hospital on Aug. 21st, 1897, with a perforating wound of the right cornea and sclera in the lower and inner quadrant. There were prolapse of the iris, hyphæma, and a traumatic cataract. A foreign body was in the globe (?). On the day of admission an iridectomy (of prolapse) was performed. A large piece of steel, measuring about ½ in. by ¼ in., was extracted by the electro-magnet through the wound. A slight escape of vitreous took place. The eye quieted down very gradually, but never regained normal tension. On Sept. 20th the vision of the right eye equalled perception of light feebly; there was no projection. Excision was advised. In January, 1898, the globe was shrunken, the tension being − 1. The pupil was occluded. Occasional attacks of pain and congestion occurred. The vision of the right eye equalled perception of light; there was no projection. The eye was excised on Jan. 18th.

B.—FOURTEEN CASES IN WHICH THE EYE WAS SAVED.

CASE 1.—A patient, aged twenty-five years, was admitted to hospital on Dec. 3rd, 1896, having been "struck in the left eye by a piece of steel" three days before admission. On ophthalmoscopic examination the foreign body was seen projecting through the sclera into the vitreous. The scleral wound was slightly enlarged and the foreign body was easily removed by the electro-magnet. On the 21st there were flaky vitreous opacities. The vision of the left eye equalled $\frac{6}{9}$ with + 2 D.

CASE 2.—A patient, aged forty-three years, was admitted to hospital on March 8th, 1887, having been "struck in the right eye by a small piece of steel" two weeks before admission. On admission there were some ciliary congestion and fine posterior synechiæ. Dense membranous vitreous opacities obscured the fundus, but a sharply-defined whitish mass of about twice the size of the disc and with an elongated blackish centre could be seen in the vitreous. The black centre was thought to be a foreign body (steel), and on applying the magnet over the surface of the eyeball the mass was seen to move about in the vitreous concurrently with the movements of the magnet. The tension of the right eye was minus. On the day of admission the foreign body with lymph adherent was removed by the electro-magnet through a meridional scleral incision. On April 28th there were vitreous opacities and the ciliary congestion had disappeared. The synechiæ all gave way under atropine. Pigmentary and atrophic changes occurred in the retina and the choroid where the foreign body had lain. The vision of the right eye equalled $\frac{6}{18}$. On June 11th, 1898, the vision and the fundus were the same as they had been on April 28th, 1897. The patient had no trouble with it and was able to work all day in front of a furnace fire.

CASE 3.—A patient, aged fifty-five years, was admitted to hospital on March 8th, 1897. "Whilst shoeing a horse fourteen days ago something struck him in the right eye." On admission a foreign body was seen in the anterior chamber. A small corneal scar was visible and there was some iritis. The foreign body was extracted by the electro-magnet through a peripheral corneal section. On the 22nd the vision of the right eye equalled $\frac{6}{9}$.

CASE 4.—A patient, aged twenty-five years, was admitted to hospital on March 12th, 1897, with a wound of the left cornea and sclera. A foreign body was in the globe. On the day of admission a large piece of steel was removed by the electro-magnet. Prolapse of the choroid and retina was removed. The sclera was stitched. On the 19th there was perception of light by the left eye on the inner side only, but on April 10th there was no perception of light. He had had recurrent hæmorrhages into the vitreous and anterior chamber. There was no red fundus reflex. The tension was normal. On July 10th, 1898, the left eye was shrunken and atrophied. The lens was opaque and there was slight ciliary congestion. There was a large depressed scar of the cornea and the sclera downwards and outwards. The vision of the left eye equalled no perception of light and the tension was minus. There was no pain or inconvenience. Excision was advised. The right vision equalled $\frac{6}{9}$.

CASE 5.—A patient, aged seventeen years, was admitted to hospital on July 30th, 1897, with a perforating wound of the right sclera above. A foreign body of the size of a small shot was visible in the vitreous. The wound in the sclerotic was enlarged slightly and the foreign body was removed by the electro-magnet. There was some reaction after this; the pupil contracted and the aqueous became hazy. On Aug. 18th the eye was fairly quiet and the pupil was nearly fully dilated. On Sept. 16th there were dense vitreous opacities and a patch of choroido-retinal atrophy with pigmented margins at the lower periphery. The vision of the right eye equalled $\frac{6}{18}$ with + 1 D. On June 11th, 1898, there were fine vitreous opacities and the patch of atrophy as above. The vision of the right eye equalled $\frac{6}{6}$ with + 0·50 D. The patient had been at work since November, 1897.

CASE 6.—A patient, aged twenty-five years, was admitted to hospital on Sept. 15th, 1897, with a perforating wound of the left upper lid and sclera; a piece of steel was supposed to be in the globe. On the day of admission a foreign body was extracted from the vitreous by the electro-magnet. On Oct. 8th there were dense membranous vitreous opacities extending from the wound in the sclera above, downwards across the pupillary area towards the lower periphery. Details of the fundus were not made out. The vision of the left eye equalled $\frac{6}{24}$ with $\frac{+\ 2{\cdot}5\text{ D. sph.}}{+\ 1\text{ D. cyl. }\phi\ 90^\circ}$ and that of the right eye $\frac{6}{6}$. On Dec. 15th the left vision equalled $\frac{6}{18}$ with $\frac{+\ 2{\cdot}5\text{ sph.}}{+\ 1\text{ D. cyl. }\phi\ 90^\circ}$.

CASE 7.—A patient, aged twenty years, was admitted to hospital on Nov. 26th, 1897, giving a history of having been struck in the right eye by a piece of steel. On the same day there were some congestion and chemosis of the eye and a small wound of the cornea extended slightly into the sclerotic below. There was a small triangular wound in the periphery of the iris opposite the corneal wound. Hyphæma was noted. The fundus was not visible. On applying the magnet a semicircular ring of steel, ⅛ in. in diameter and $\frac{1}{16}$ in. thick, was removed from the ciliary region. It was a little difficult to extract such a large body through the small wound, but after getting the piece of steel attached to the magnet by one end it came out, the magnet being gradually rotated as the ring emerged. There were some chemosis and iritis for a few days after the removal of the foreign body. On Dec. 14th the eye was quiet. A small detachment of the retina at the lower periphery had taken place and there were numerous vitreous opacities. The vision of the right eye equalled $\frac{6}{9}$ with + 3 D. The patient was discharged from the hospital. On the 21st the eye was quiet. There were membranous vitreous opacities and a detachment of the retina (lower and outer half) implicating the yellow spot. A semicircular ring of choroidal atrophy was observed at the site of the foreign body in the lower periphery. Fingers could be seen with the right eye at a distance of 1 metre. The patient refused to re-enter the hospital for further treatment and has since left the neighbourhood and is quite satisfied with his eye as it is.

CASE 8.—A patient, aged twenty-one years, was admitted to hospital on Nov. 27th, 1897, with a right traumatic cataract. A foreign body was in the lens. On the 30th the foreign body was extracted by the electro-magnet. On Jan. 3rd, 1898, the right lens was evacuated. On August 6th the eye was perfectly quiet and normal in appearance. The vision of the right eye equalled $\frac{6}{9}$ with + 12·50 D. sph.

CASE 9.—A patient, aged twenty-eight years, was admitted to hospital on Jan. 22nd, 1898, having been "struck on the right eye by a piece of steel" on the day of admission. On admission it was found that he had a perforating wound of the right lid and sclera. There was hæmorrhage into the vitreous and probably a foreign body was present in the globe. On the day of admission a triangular piece of steel, $\frac{6}{18}$ in. long and $\frac{1}{18}$ in. at the base, was extracted from the vitreous by the electro-magnet. No difficulty was experienced and no great disturbance of the vitreous was caused. On Feb. 9th the hæmorrhage into the vitreous was nearly all absorbed. There was almost

Digitized by Google

complete detachment of the retina. The vision of the right eye equalled perception of movements of the hand. On August 3rd, 1898, the eye was quiet, there was no pain, and the detachment continued as above. With the right eye fingers could be seen at a distance of 2 metres.

CASE 10.—A patient, aged forty-one years, was admitted to hospital on Feb. 8th, 1898, with a history of having been struck in the right eye by a piece of steel on the previous day. A large ragged wound was found in the sclera above and there was in all probability a piece of steel in the vitreous. On introducing the magnet through the wound a considerable amount of blood-stained serum escaped. On withdrawing the magnet it extracted a ragged piece of steel, $\frac{1}{8}$ in. by $\frac{1}{4}$ in., covered with a layer of whitish puro-lymph. A stitch was inserted into the sclera and the conjunctiva. On the 9th the eye was quiet except around the wound. There was a slight sloughing of the edges of the wound and congestion of the conjunctival and scleral vessels around the wound. On the 21st there was slight bulging at the site of the wound. The eye was perfectly quiet. There never was any reaction in the deeper structures of the eye. Dense membranous vitreous opacities occurred but no detachment of the retina. The vision of the right eye equalled $\frac{6}{12}$ with + 1 D. The patient was discharged from the hospital.

CASE 11.—A patient, aged forty-four years, was admitted to hospital on Feb. 8th, 1898, with a perforating wound of the left sclerotic; there was hyphæma and a foreign body was on the iris. The foreign body, a small triangular piece of steel, was extracted through the wound by means of the electro-magnet. The iris was replaced. On the 16th the vision of the left eye equalled $\frac{6}{6}$ with + 2 D. The pupil was round. On July 8th, 1898, the left vision was $\frac{6}{6}$ with + 50 D. There was a small spot of discolouration of the iris at the site of the foreign body. The pupil was round.

CASE 12.—A patient, aged twenty-four years, was admitted to hospital on Feb. 24th, 1898, having been "struck in the right eye by a piece of steel" on the day before admission. There was a small wound of the upper lid near the margin and also a small perforating wound of the sclerotic about $\frac{1}{4}$ in. behind the corneal margin above. Marked chemosis was present around the wound and on the inner side of the globe. The cornea was clear and there was a good anterior chamber. The iris was active and well dilated under atropine. The lens was clear. A large triangular membranous hæmorrhagic mass was seen lying in the vitreous. Extensive detachment of the retina was visible on the outer side. The rest of the fundus was not visible. The vision of the right eye equalled perception of light and the tension was − 1. On the day of admission a piece of steel embedded in a clot of blood was extracted by the electro-magnet. The magnet had to be inserted three times before the foreign body was extracted. On March 3rd fresh hæmorrhage into the vitreous occurred. The tension was normal (?). On June 30th, 1898, there was perception of light in the right eye. The pupil and the iris were normal and the eye was quiet and painless. Complete detachment of the retina had taken place and there were streaky hæmorrhages over the retina. The lens was clear.

CASE 13.—A patient, aged fourteen years, was admitted to hospital on April 20th, 1898, with a foreign body in the left anterior chamber which was extracted through a peripheral corneal section by means of the electro-magnet. The iris came out slightly and was afterwards replaced. On the 28th under atropine the pupil was round. The left vision equalled $\frac{6}{6}$ with − 0·50 D.cyl. ⊖ 180°. On June 30th the pupil was egg-shaped owing to a small mass of rust-coloured lymph having become adherent to the cornea and the iris.

CASE 14.—A patient, aged forty-eight years, was admitted to hospital on July 6th, 1898, having been "struck in the left eye by a piece of steel" three days before admission. There was a small wound of the sclera close to the corneal margin downwards and outwards. There were slight conjunctival injection around the wound and slight hyphæma. The iris was active and the pupil was round. There was slight haze of the vitreous downwards and outwards. A glistening triangular body was seen projecting just behind the iris on ophthalmoscopic examination with the pupil fully dilated. On the 9th a piece of steel, $\frac{1}{16}$ in. by $\frac{1}{16}$ in., was extracted by the electro-magnet from the ciliary region through a meridional scleral incision. There was considerable difficulty in extracting this foreign body. The magnet had to be introduced five times before the piece of steel became attached. On the 19th there was considerable conjunctival and ciliary congestion, which was persistent, and there was an inflammatory deposit on the back of the lens. On the 22nd the eye was quiet; the deposit on the back of the lens was still marked. The left vision equalled $\frac{6}{36}$. On August 4th the left vision was $\frac{6}{18}$ and the deposit on the lens was much less.

An analysis of the above cases gives the following results: eyes lost (including Case 4, Group B) 5; cases in which the shape and appearance of the eye have been preserved but only a small though useful amount of vision has been retained, 3; and cases in which good vision (from $\frac{6}{18}$ to $\frac{6}{6}$) has been retained, 10. Of these 10 cases 4 were in the anterior chamber or lens and 6 were in the vitreous.

As regards complications: suppuration occurred in 2 cases; detached retina in 3 cases; shrinking of the globe in 2 cases; recurrent hæmorrhage into the globe in 1 case; and deposit on the posterior surface of the lens in one case. It is noteworthy that not a single case developed sympathetic ophthalmia.

C. SIXTEEN CASES IN WHICH THE ELECTRO-MAGNET WAS INTRODUCED INTO THE EYE, BUT NO FOREIGN BODY WAS FOUND.

Of these 16 cases the eye was lost in 3 (excision advised in 1 other case); there were 7 cases in which the shape and appearance of the eye were preserved but with little vision; and in the remaining 6 cases good vision (from $\frac{6}{18}$ to $\frac{6}{6}$) was retained.

In the 3 cases in which excision was performed the foreign body was found to be embedded in the choroid in 1 case and in the optic nerve and sclerotic in the other 2 cases.

Owing to the incompleteness of the records 7 does not represent accurately the number which ought to be included in the second category. 3 out of the 7 are noted as having traumatic cataracts when discharged. These, if they had been operated upon, would probably come to be arranged with the last group. The complications noted in these cases were as follows: detached retina occurred in 2 cases; deposit of rust-coloured spots in the lens capsule in 1 case; and iridocyclitis followed by synechiæ posterior and iris bombé in 1 case. Here, again, there is no record of sympathetic ophthalmia as a complication.

It remains to explain why there is such a large number of cases in which the electro-magnet failed to extract the foreign body which was presumed to be in the eye. Some of the cases probably did not contain a foreign body. Such as these one hopes in future to be able to eliminate by the adoption of additional and improved methods of investigation, such as the use of the sideroscope, Haab's magnet, and the Roentgen rays. Judging from cases already published and from recent cases of our own I think skiagraphy promises to supersede all other methods. More accurate localisation would also help to reduce the number of failures, as the magnet could then be passed towards the exact spot at once, and there would be less likelihood of the object being missed or of its failing to become attached when surrounded by lymph or blood. Thus the surgeon would also minimise that disturbance of the vitreous and other structures of the eye which proved so detrimental in at least one of the above cases. Skiagraphy employed on the lines laid down by Mr. Mackenzie Davidson has proved a most accurate localising agent. In a certain number of cases the foreign body was undoubtedly firmly embedded in the coats of the eye and in these cases a powerful magnet such as Haab's might have been more successful than the small magnet, or having carefully localised the object by the means above mentioned an incision could be made directly over its site and the foreign body extracted by magnet or forceps.

In conclusion, I wish to thank the honorary surgeons of the hospital for their kind consent to publish these cases and my predecessor, Mr. Minnes of Kingston, Ontario, for many of the notes.

Birmingham.

NORTH DEVON INFIRMARY, BARNSTAPLE.—The annual meeting of the North Devon Infirmary was held on August 16th. The report showed that during 1897 the out-patients numbered 2722 and the in-patients 677, the average daily number in hospital being 43 and the average stay 26 days. The total ordinary expenditure was £2515 and the ordinary income was £2008.

THE CONSERVATIVE SURGERY OF THE OVARY.[1]

BY CHRISTOPHER MARTIN, M.B. EDIN., F.R.C.S. ENG.,
SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

THE physiological value of the ovaries may be best realised by noting the results of complete extirpation of both glands. (*a*) The woman becomes absolutely sterile; (*b*) menstruation ceases in about 95 per cent. of the cases; (*c*) the uterus and to a less extent the vagina and vulva undergo a process of atrophy; (*d*) the nervous symptoms of the menopause appear abruptly and violently—viz., heats and flushes, perspirations, palpitations, giddiness, depression of spirits, and a generally unstable condition of the nervous system; (*e*) in a considerable majority of cases there is a diminution or total abolition of the sexual instincts; and (*f*) the patient has a tendency to obesity. Now, if one ovary, or even only a portion of one ovary, be left behind none of these symptoms appear. There is physiologically no difference between a woman with half an ovary and a woman with two ovaries, while there is a great difference between a woman with half an ovary and a woman with none. It is remarkable how small a fragment of ovarian tissue is necessary to preserve the full influence of the gland on the body. Let me now very briefly direct your attention to certain operations on the uterus and its appendages, in which, by a little care, the surgeon may preserve the ovary and at the same time cure the patient.

In the first place, I need hardly point out that in cases of ordinary cystoma of one ovary—the other ovary being healthy—it is unjustifiable to remove both ovaries. If, however, the case be one of sarcoma of one ovary, then I think it is not only justifiable but that it is the surgeon's duty to remove both glands even if to the naked eye the other ovary appears normal. A sad experience of these cases shows that sarcoma is extremely apt to affect first one ovary and then the other. By taking away both I think we diminish the chances of recurrence. In cases of inflammatory diseases of the uterine appendages (salpingitis, pyosalpinx, ovarian abscess, &c.), if the disease be confined to the organs on one side only it is unnecessary to remove them on both sides. I have frequently removed the uterine appendages on one side only for inflammatory disease, leaving the appendages on the other side alone, or if adherent, merely freeing them. The results have been most satisfactory, and I have not in a single case had to remove the remaining appendages at a subsequent operation. The following is an illustrative case.

On Feb. 3rd, 1896, I operated on a woman, aged twenty-five years, with a large inflammatory mass to the right of the uterus. Her illness dated from her confinement several months previously. At the operation the mass proved to be an ovarian abscess, and I removed the diseased (right) appendages. The left appendages were buried in plastic lymph but not otherwise obviously diseased. I therefore contented myself with freeing them from adhesions. The patient made a good recovery, but for some time the pelvic roof remained fixed and indurated. Gradually, however, all signs of past inflammation melted away. Twelve months after the operation nothing abnormal could be detected on vaginal examination, and she was symptomatically cured. Early in July, 1898, she came to tell me that she was three months pregnant and in excellent health.

In cases of double pyosalpinx it is now my custom to perform vaginal hysterectomy and at the same time to remove the diseased tubes. In such cases I always endeavour to leave behind one or both ovaries unless they are obviously diseased. After removing a large fibroma of the ovary I was struck, when I came to examine the specimen, by the fact that the fibroma had developed in the medulla of the ovary and had spread out the glandular portion of the ovary (the cortex) as a thin sheet or capsule on its surface. It was quite easy to shell out the fibroma from this follicular capsule. The fibroma, in fact, was a mere foreign body growing in the substance of the ovary, displacing but not infiltrating its true glandular substance. In another case after I had removed an ovary of about the size of a hen's egg I split it open and found that I could easily shell out of its substance a small fibroma. In both of these cases it would have been easy to have saved the ovarian tissue proper by incision of the ovary, enucleation of the contained fibroid, and suture of the capsule. Since then I have examined numerous specimens of fibroma of the ovary, and in all of them I find the same relationship of the tumour to the gland.

Early in 1898 I had to operate on a young lady, aged twenty-six years, suffering from dermoid tumour of both ovaries. She was engaged to be married and was anxious, if possible, that one ovary should be saved. I found that the left ovary was the seat of a dermoid cyst of the size of a cocoanut, whilst the right ovary contained a dermoid cyst of the size of a hen's egg. I removed the left ovary entirely; but I found that I could easily shell out unruptured the small dermoid cyst from the substance of the right ovary and thus preserve about three-fourths of its glandular substance. I sewed up the incision in the right ovary with fine cat-gut. The patient made a good recovery. That the portion of ovary left behind was of physiological value is shown by the fact that since the operation she has menstruated regularly. Had I removed both ovaries she would have broken off her engagement to be married, whereas now there is no reason why she should not marry and become a mother. In a few cases where patients have been the subjects of cystic disease of both ovaries I have removed the ovary which was the more diseased and have performed resection of the ovary which was less affected. In these cases I found that the cystic disease affected only one pole of the ovary. I was able to remove a wedge which included all the diseased tissue and then to sew up the V-shaped gap by a fine continuous silk or catgut suture. The ovary seems to contain capillary blood vessels only; I certainly never had any trouble with hæmorrhage from the divided ovarian tissues. In this way I have now performed resection of the ovary in 5 cases and in all of them with the most satisfactory results. I have had the cases under observation for periods varying from four months to four years and in not one of them, so far, has there been any sign of recrudescence of the disease. 3 of the 5 cases were those of young unmarried women, aged respectively twenty years, twenty-five years, and twenty-six years; while 2 were married and were aged twenty-two years and thirty-three years. In all the 5 cases the preservation of even half an ovary was a matter of importance to them.

I know of no pelvic condition more troublesome to treat than that known as chronic ovaritis. It is associated with, if it be not the cause of, severe dysmenorrhœa, menorrhagia, ovarian neuralgia, hysteria, anæmia, and other disorders. The conscientious gynæcologist tries drug after drug and remedy after remedy with but discouraging results. Finally, in a considerable proportion of the cases he is driven to do something by way of operation to relieve the patient's sufferings. In the past in too many cases both the appendages have been removed, and in a large proportion of these I doubt if the patient has been much benefited by the operation. Menstruation usually ceases but the patient's sufferings continue. As an alternative the conservative operation of ignipuncture is well worth a trial. It may be done by vaginal section by either anterior or posterior colpotomy. The peritoneum having been opened any adhesions binding down the ovary are separated with the finger. The ovaries one after the other are then drawn into the vagina and punctured with the fine point of Pacquelin's cautery heated red-hot. Wherever there is an indication of a cyst in the cortex or an unusually thick portion of the capsule of the ovary the red-hot point is inserted. In this way from six to a dozen punctures, each about $\frac{1}{2}$ in. in diameter, are made in each ovary. The appendages having been replaced in the peritoneal cavity the vaginal wound is closed with catgut and the patient is put back to bed. I have now performed this operation of ignipuncture for chronic or cystic ovaritis 14 times. All the patients made an easy recovery from the operation. In 5 cases the operation failed to cure the patient, and in 3 of these I had subsequently to perform the operation of removing the appendages. One case has been operated on too recently for me to judge as to whether or not it will succeed. Of the other 8 I have been able to trace all but one patient, leaving 7 cases in which a cure has

[1] A paper read in the Section of Obstetrics and Diseases of Women at the meeting of the British Medical Association at Edinburgh, July, 1898.

Digitized by Google

certainly resulted. One of these 7 was a woman who had been married for five years but had never been pregnant. She became pregnant three months after the operation, and was confined at the full term of a living child.

If a parovarian cyst be examined in its early stage it will be found lying in the substance of the broad ligament quite distinct from the ovary proper. In some cases it is pedunculated and in others it is more or less embedded between the two layers of the broad ligament. In these early cases it is very easy to remove the cyst without removing the ovary. Where it is pedunculated the pedicle can usually be tied without including the ovary; where it is embedded it is not difficult to split the peritoneal capsule and shell the cyst out from between the two layers of the broad ligament. The wound in the broad ligament is then closed with a fine continuous silk suture. In more advanced cases the ovary is often spread out as a thin sheet over a portion of the posterior surface of the growth. Even here it will often be found an easy matter to split the capsule of the cyst and peel off the ovary from its posterior surface. If the other ovary be quite healthy this attempt to save the ovary on the same side as the cyst is perhaps unnecessary, if by so doing the surgeon at all increases the gravity of the operation. If, however, the other ovary be absent or have to be removed, then the surgeon should endeavour to save the ovary in removing the parovarian cyst. In cases of embedded cysts of the broad ligament, the surgeon is compelled to enucleate the cyst from between the two layers of the broad ligament, and then, *nolens volens*, he preserves the ovary intact.

If the uterus be completely removed of course the patient becomes sterile and menstruation ceases, but if at the same time one or both ovaries be left behind the nervous symptoms of the menopause are slight and often entirely absent. If, however, both ovaries be removed with the uterus these symptoms appear. I have observed, however, that patients who have had the uterus removed as well as the appendages suffer from climacteric troubles less severely than do those who have had the appendages alone removed. In some mysterious fashion the uterus bereft of its appendages is a source of disturbance to the nervous system. I have come to the conclusion that if both ovaries and tubes have for any reason to be removed it is better at the same time to remove the uterus. On the other hand, if the uterus has to be removed we should endeavour to preserve one or both ovaries.

It would be out of place in this paper to discuss at length the relative merits of the various surgical methods of treating uterine myoma. In my own hands panhysterectomy and vaginal hysterectomy have proved themselves much safer than either the removal of the appendages or the old clamp operation. An important argument in favour of hysterectomy is that it is generally easy to preserve one or both ovaries, whilst, of course, the essence of the removal of the appendages consists in their sacrifice. In abdominal hysterectomy, either where the old "clamp" operation or the more modern method of "panhysterectomy" is performed, it is generally easy to pass the uppermost ligature between the ovary and the fundus. The ovary is thus left on the proximal side of the ligature and has its nutrition maintained by the intact ovarian artery and veins. Similarly in cases of vaginal hysterectomy the upper ligature should be passed on the uterine side of the ovaries in order that they may be preserved. I have now performed abdominal hysterectomy for various conditions 42 times; 13 of these were "clamps" and 29 were panhysterectomies. In 27 cases I removed both ovaries with the uterus and in 15 cases I was able to leave one or both ovaries behind. I have performed 40 vaginal hysterectomies for various conditions. In 13 cases I removed both ovaries with the uterus and in 27 cases I was able to save one or both ovaries. I have been able to trace the after-history of most of these cases and I do not know of a single instance in which this conservation of the ovary has led to any untoward result.

In conclusion I would urge gynæcologists to give a fair and unbiased trial to the conservative surgery of the ovary. The reckless way in which in the past uterine appendages have been removed without adequate justification is the opprobrium of our art. The profession owes therefore a debt of gratitude to men like Pozzi of Paris and Martin of Berlin for their pioneer work in conservative surgery as applied to these organs. The brief account I have given is a summary of my own endeavour to follow in their footsteps, and I trust that it will encourage other gynæcologists to give a fair trial to these conservative measures.

VITALITY:
AN APPEAL, AN APOLOGY, AND A CHALLENGE ADDRESSED TO BROTHER PRACTITIONERS.

BY

LIONEL S. BEALE.

(Concluded from page 407, August 13th.)

THE INNER LIFE OF THE BIOPLASM.

So far in this appeal I have kept pretty strictly to comments upon the results of actual observation—facts I have observed, things I have seen with my own eyes, that I can see now, and can show to others; or to appearances which I can very distinctly remember, many of which will remain in my memory as long as it may last; but under the above heading I pass towards another realm in which I cannot be entirely guided by fact and observation. At the entrance, perhaps, they only wait.

Of the existence of the inner life of the bioplasm I have no more doubt than I have of the ordinary growth of living things known to all, but to see the changes which take place in the matter of a minute particle of bioplasm is at present possible only to the mind.

Notwithstanding the increased facilities we enjoy of using high magnifying powers and the large experience of their value recognised by hundreds, very little, I regret to say, has been recently added to our knowledge concerning the minute changes which occur in the very substance of every kind of living bioplasm. Nor do I think that we should be able to see much more of the inner phenomena of the bioplasm itself even if our magnifying powers were increased to ten thousand diameters—that is, an increase which, if it were possible to effect in all parts of the body at once, would make the magnified man appear many miles high.

The study of bacteriology has familiarised students with the use of high magnifying powers, but as yet comparatively few observers have used these high powers for the study of the tissues of man and the higher animals and for the investigation of the changes occurring during development. Further experience in the use of glycerine for examining and preserving animal tissues will, I think, lead to many demonstrations of the greatest interest and importance, for in some such way only can the bioplasts and the more delicate tissue elements be saved from pressure, just as they are all protected and supported by the interstitial fluid in the natural state during life.

Bioplasm, as I have already endeavoured to show, is the only living matter in the organism, and by it all formative changes are effected. Healing processes can take place only through the agency of living matter. Not only do all vital "properties" and powers, all inherited characters, all modifications in structural details, whether arising anew or inherited, depend upon bioplasm, but every kind of evolution in living things is rendered possible only by the existence and activity of this living matter.

The matter of the universe which has never been in the living state and can never live is overwhelming, indeed infinite in proportion to that which might live. The quantity of matter that *may* form a part of living things is so minute as to be inappreciable in the mighty operations and changes in the mass of Cosmos.

Though the matter that actually lives in organisms is so inconspicuous in appearance and insignificant in quantity that it often passes unnoticed, its marvellous inexplicable powers by which the rearrangement of non-living matter and the unaccountable changes effected in its behaviour have been the cause of wonder and astonishment of all philosophical observers and thinkers. Vital power exists in relation with all the minutest particles of living matter and there cannot possibly be any quantitative relation between the matter and the vital power by which it is influenced.

Since a particle of living matter so minute that probably twenty such or more would not weigh down a single red blood corpuscle, and that very minute living speck containing more than 90 per cent. of water, may be the means of conveying vital power which may afterwards influence enormous quantities of matter and afford evidence of its derivation, I must firmly cling to the idea of vitality being a power

Digitized by Google

belonging to the living world only—a power which, so far from originating in the non-living, actually controls it and causes it to exhibit structure, alters its composition, and brings about many changes that cannot be induced in any other way—changes that are known only in the living world where *Vital Power* reigns supreme.

A particle of living matter may, in fact, be far less than $\frac{1}{100,000}$ in. in diameter, the power of which may be handed down for ages, and make its presence evident by its effects upon the composition and action of such enormous quantities of matter that probably no one who thinks about the facts will again declare that it is the infinitesimal particle of *matter and not the mysterious scientifically (!) indefinable power temporarily associated with it* to which its so-called actions, consequences, or effects are due.

The positions and relations of the innumerable particles of living matter among the tissues of complex organisms have already been pointed out and attention has been drawn to the facts which have led me to conclude that the difference between every form of living matter and every form of non-living matter *is absolute*, and that there is no relation of degree between these two states of matter, while all the evidence obtainable at this time is opposed to the dogma that "the living and the non-living are one." The phenomena which characterise all living matter, among which *movement, growth, selection, analytical power, and arrangements for synthesis* are pre-eminent, must be attributed to Vitality, while the formation of tissue and other formed matters has been shown to result from the *cessation of vital action*—in fact, the death of the particles that were living.

But besides the living particles in all the tissues and organs of the body, there are suspended in the blood, lymph; and chyle continually circulating with these fluids extremely minute bioplasts whose office it probably is to take up various substances dissolved in the fluids and thus assist in regulating the composition of the nutritive juices as well as discharging other important offices. Similar minute bioplasts also exist in the interstitial fluid, which circulates in the interstices of all the tissues and in and around the particles of bioplasm. In certain abnormal conditions these may grow and multiply and cause serious departures from the healthy state.

The rate of increase, and necessarily the quantity of non-living matter becoming living, is not uniform, in every part of a particle of bioplasm, or within the same period of time. In some situations, probably towards the centre of centres already existing, new centres appear which do not mingle with the adjacent bioplasm. It is, I think, in this way, both in health and disease, that not only one but many "nuclei" and "nucleoli" make their appearance in already existing bioplasm.

The vital power acquired by a new centre which was developed very slowly may be far greater and more comprehensive, and farther, much farther reaching, than that possessed by the bioplasm in which it arose. If the conditions are favourable and the nutrient matter abundant, the processes of growth and multiplication of bioplasm proceed rapidly, while if the conditions be more or less adverse the increase and the development are correspondingly slow. In the first case, however, the higher, the formative, the constructive, the tissue-forming power of the bioplasm is slight or may be completely lost, and the rapid multiplication may soon result in the production of bioplasts in great numbers which are very shortlived; and the entire number may soon die. In the last case, in the new centres may subsequently arise others, the bioplasm of which goes on growing and in certain instances multiplying very slowly and after some time may give origin to bioplasts which will take part in the formation of complete tissues and organs and perhaps become the parents of important and complex living tissues or organisms. Thus it may, I think, almost be held that there is somehow either a new origin or a mysterious concentration or evolution of vital power.

Only consider the complex arrangements and the long period of time which elapses before their completion, required for the evolution of germ and sperm bioplasm, particularly of the higher organisms; yet how minute is the active bioplasm particle when at last its evolution is complete, and how wonderful is, as it were, the concentration of vital power! Have we not here an example of the maximum of vital potency associated with the minimum of matter? The power seems to have been acquired not from already existing living particles, but to have been evolved as centres appeared within centres, and the result of these wonderful processes—the end—seems to have been anticipated and provided for, foreseen, as it were, from the first. This wonderful example of a very minute living particle in which amazing vital power is associated with an infinitesimal amount of matter—"a product of secretion" formed according to physiological laws! But is it not time that we were allowed to contemplate a great biological fact without making ourselves physiologically ridiculous?

Supposing the successors of primitive living organisms to have been variously modified in the course of thousands or millions of generations to the extent conjectured by some naturalists, as their environment, food, &c., have undergone modification; it is, I think, nevertheless certain that the broad characteristics of the living matter, its mode of growth, the manner in which it takes up nutrient matters into its very substance, rearranging their constituents and gradually, perhaps, undergoing conversion into tissue and other formed matters—those wonderful vital actions, potencies, powers—call them what you will—absolutely and fundamentally differing from any phenomena, properties, tendencies, possibilities or potentialities, that have been shown to exist or have been ascribed to any form of non-living matter yet discovered or supposed to exist—are still retained. And are we any nearer to anything approaching a reasonable explanation of the formation of living things and their changes if when we carry our thoughts back to the remotest past the imagination can conceive—if you will, long ere the first amœba particle began to stir or cilium to vibrate? The gulf between the living and the non-living must have then been as wide and as unfathomable as it is to-day, and as unbridgeable as when the first infinitesimal living particle burst forth into vital activity alone (?) in the universe of everlasting cosmic matter, as it is now when almost every spot upon the surface of our earth is peopled with evanescent but never-ceasing infinite life of very different endowments and powers.

Guided by the results of actual observation and by reasoning, with regard to the inner vital phenomena of all bioplasm we now come to this: in all life there seems to be movement of matter, movement in a direction *from centres* where vital power is communicated, the matter before it began to live having been caused to move *towards* the centre where some of its constituents having come into contact with the actually living matter—live. Now movement takes place in the opposite direction *from* centre. If we are to conclude that the centripetal movement of the non-living matter is in obedience to a law, may I not—nay, am I not forced to—conclude that the centrifugal movement of the matter now living is independent of or overcomes that law? Living particles for the time not only move notwithstanding the influence of gravitation but seem unaffected by this and some other *laws* to which every form of non-living matter is subject.

The surpassing interest of the problem must be my apology for venturing to lay before the profession the views which have presented themselves to my mind in the attempt to learn as much as possible concerning that mysterious agency to which I would limit the term *vitality*, or *vital power*, or *life*. But these words have so long had a much more general signification that I should like to find a word which might be applied to this mysterious factor which I not only feel compelled to acknowledge but hope to convince many other observers of the existence. Though offending against etymology, may I venture to coin a convenient word by help of Greek and German—the most philosophic of ancient and modern languages—Biokraft—in the sense I use "vitality" and "vital power"?

From the bioplasm which constitutes the earliest speck which represents man or any animal to that of which the degenerate pus-corpuscle is composed—bioplasm which has for ever lost all formative constructive power, but may multiply exceedingly and rapidly—the inner life of the bioplasm, the wonderful vital changes in essential nature and characters alike, are carried on in centres so central as to be invisible to us with the aid of the highest powers at present obtainable. It is here that the communication of wonderful power from the already existing bioplasm to the new matter actually occurs.

Difficult indeed is it to discover, even to imagine, any *laws* already defined, which govern, regulate, or account for the phenomena of the matter concerned in the inner life of the bioplasm. What evidence can be advanced in favour of the operation of gravitation in these and other vital changes,—of cohesion, of affinity, of proportion? Are not

Digitized by Google

heat, light, and electricity evolved in living organisms under conditions totally different from those which obtain when these are evoked in the non-living world—different indeed from those existing in any laboratory? Many facts connected with life are known and new facts are continually being discovered, but what is known concerning *laws* that govern the evanescent living state? The instant death has occurred the dead matter is subject to the operation of ordinary law.

The constitution of each living particle in nature is probably constantly changing, and even in the case of living particles which seem to retain their vitality for a long period it is more probable that vital changes are constant than that all change ceases even for a moment. Vital change continues without a moment's interruption in cases of extremely prolonged "hybernation." In a living particle sometimes much, sometimes little, of the nutrient matter is appropriated. In some cases if the products resulting from the death of living matter unduly increase to its detriment, and if not soon removed may cause its destruction. In the perfectly normal condition, however, neither the living matter, nor the non-living matters about to live, nor those that have lived disturb the balance.

Undoubtedly, as already remarked, while we contemplate the phenomena of the inner life of the structureless bioplasm or living matter we enter upon the consideration of what is at least at present beyond demonstration. It is here, if I mistake not, is hidden the mystery of mysteries of life and of all living nature. Though to my mind there seems but one conclusion possible, it is pretty certain that this conclusion will at present be accepted by few.

I therefore plead for free and open discussion of this great question of vitality from the point of view I have indicated, for whether what we have so far learned concerning the secrets and mysteries of living nature leads, or tends to lead, us towards the conclusion that all life is but a necessary outcome of everlasting matter, of the cosmos, of the universe, and is determined by eternal laws coeval with origin—or to the conclusion that the first creation of life is a comparatively recent introduction—an addition just limited to the external layers of our earth, and therefore bearing but a very insignificant proportion to the whole matter of which our world is made, the question is surely worthy of debate. It has been considered by the most thoughtful of many generations during thousands of years and cannot be regarded either as already determined or so sacred and so absolutely insoluble and so utterly beyond the comprehension of the best, the wisest, the most intelligent of men, as to be regarded as for ever beyond the capacity of the human understanding, and therefore an altogether impossible and hopeless inquiry. Again, let me press upon my readers' attention that during the last half-century the circumstances are wholly changed. Our knowledge of minute structures increases year by year. No one can compare the recent editions of standard works upon microscopic anatomy with a book published twenty years ago without being convinced of the great progress of minute anatomical investigation, though there is nevertheless much difference in opinion concerning many of the most important and fundamental questions which we ought to endeavour to determine by fresh investigations and other methods of preparation.

But if it were set aside by authority and the general concurrence of the thoughtful, or even forbidden by some law carried by a two-thirds majority, it would only be for a very few years that inquiry could be stifled or stopped or deemed by general consent to be wicked or declared illegal. It is certain that among us at least some few would still remain rebellious and as determined as hundreds and thousands before to study living nature in their own way, with the aid of the best instruments of research that could be obtained, and bring their observations, their conclusions, nay, their conjectures, before their fellow students of natural knowledge. On such grounds every real student would seem to have a right to ask for the patient consideration and discussion of the results of his investigations by his fellows, and a right of appeal against the dictation and authority of any party that happens to command for the time what has been called the general assent of all intelligent persons, nay, notwithstanding another doctrine had been accepted by an enormous majority and propagated as a new religion.

I appeal against the acceptance and absolutely decline to accept any mere physico-chemical hypothesis of life whatever, or the dogmas that life originated in matter, that life and non-life are governed by the same "laws," and that the living is but a form of the non-living. I plead, further, that scientific conjectures on both sides of a great question like this ought to be thoroughly considered.

Whatever may be the explanation, for more than thirty years past the views, the assertions, the working hypotheses, the conjectures, the assumptions of those who declare for purely physical doctrines of life have unquestionably been afforded advantages which have been most unreasonably and most unfairly denied to those who differ from them; not only so, but it has been shown that many doctrines now accepted on the ground that they are supported by reason are and have been absolutely opposed to reason from the first, and cannot be entertained by anyone whose views are guided by reason—such, for example, as the dogmatic assertion "man is a machine," "growth is a form of aggregation," and many, many more which have been collected and criticised in "Protoplasm." For nearly half a century there has been a dead set nearly everywhere in favour of purely physical doctrines of vital action, which from the very first have been scientifically untenable.

It is not known to what degree of minuteness the division of particles having all the vital powers and properties of the organism and infinite powers of growth and multiplication, might be carried without destruction. On the other hand, the undoubted fact of the vital influence of an excessively minute particle of parental bioplasm in causing vast quantities of matter to be so arranged that it assumes not only the general form and character of one or both parental organisms from which it was derived, but likeness in many minute details—likeness in form and colour, in feature, likeness in thought, in action, likeness extending even to the form and character of some of the less important organs and tissues—one would rather infer that at least in man and the higher organisms there was a point beyond which division would mean imperfection in subsequent vital processes or absolute destruction of life. But the degree of minuteness to which I refer is probably in many instances less than the $\frac{1}{100,000}$th of an inch. The nature and far-reaching influence of vital power carried and represented by so excessively minute an amount of matter is almost staggering and yet there seems little doubt that the conclusion ought to be accepted.

The evolution of centre within centre, the emanation of new centres in centres more central than has ever been seen, is, as I have said, not demonstrable. Nevertheless, various considerations render it highly probable that the new vital powers are communicated to the non-living material particles in a state of division so minute as at present to be far beyond our means of investigation, but the idea seems to be in accordance with reason. It is probable that here occurs the separation from one another and the rearrangement of the elements (?) of various substances which occur in all living—a rearrangement effected by that power which has so far eluded investigation—the impossibility of the existence of which has so often been confidently proclaimed.

It is in these invisible centres of living matter that vital power to which the natural characteristics of organisms made manifest long afterwards is active; also those new endowments which are the cause of the appearance of new characters visible at a later period in the fully-formed organism and powers inherited from pre-existing organisms are imposed. This, as it seems to me, is indeed the only situation where, and the only time when, the *evolution* of all developmental peculiarities, differences of form and structure, must be determined—long and long before the slightest evidence of any changes in character can be indicated, and it seems to me that it is not possible to conceive such a living centre without a circumference, and the idea therefore involves the occurrence of never-ceasing phenomena the very reverse of those which are presented to the mind of the astronomer.

Such are, I venture to suggest, the conjectures of what probably occurs in the unseen and so far invisible centres of living matter, which have presented themselves to my mind as reasonable. I have only ventured to consider them in the hope of lighting upon some hypothesis which may help us to pursue further the wonderful possibilities of the inner life of particles of living matter, the existence of which is almost forced upon the mind that tries to penetrate into the innermost mysteries of vital evolution.

Question of a vital unit.—Considering the above points one feels inclined to inquire whether or no there can be a physical or chemical atom incapable of further division or capable of infinite subdivision—by the agency of vitality; and to

Digitized by Google

speculate as to the point when the subdivision of living matter begins to effect reduction, and at length destruction, of vital power. Though feeling almost hopelessly incompetent to attack so difficult a problem I cannot resist the temptation of again referring for a moment to the question of a vital unit. Of elementary organs there can be no doubt, for every complex organ is made up of such units, though we cannot anatomically separate one from its neighbours, and it is impossible to isolate one in an active state, but in some of the so-called lower forms of life they are so developed and can be examined—units concerned in function being demonstrable.

But the most important of all is not actually separable and demonstrable, though I consider it is established by anatomical evidence. In man and complex organisms in which the nervous system is highly developed nearly all such inseparable units extend without any solution of continuity rom nerve-centres to the ultimate peripheral distribution of the finest nerve-fibres and their bioplasts; and, as I think I have made out, *back again* to the central bioplast, the so-called nerve-cell. I have tried to prove ends and end-organs in which nerves end and have utterly failed. I therefore still must hold to the existence of complete circuits in every nervous system and believe the very simplest—the unit, the elementary nerve-organ, is a complete and *uninterrupted circuit*.

Although, as already stated, the division of living matter may in some cases be carried wonderfully far without any loss whatever in power, there must be a point beyond which division could not be carried without death. Looking at the structureless, colourless, moving, living matter, say, of an amœba or a mucus corpuscle, one would necessarily feel it difficult to regard a minute portion of a semifluid substance capable of movement in all directions almost like a portion of water, as a unit. It is quite impossible to form an idea of the size beyond which division without destruction is possible in all cases, and it is probable that the size would differ in different kinds of living matter, and perhaps in the same kind in different states, as, for example, during a period of active nutrition and growth, and at a time when these vital processes were very slowly performed. I incline, therefore, to the view that there is a vital element, a vital unit not mathematically fixed, but, like all living, capable within certain limits, of variation in size, and rate of growth, without detriment. From the chemical point of view I cannot imagine a living molecule of definite chemical composition or of definite atomic constitution; for all living matter seems to be the seat of incessant change, physical and chemical; governed, regulated, and determined by vital power.

A living atom is, to my mind, impossible in thought, for is not the idea of living without moving, without constant changing of the relative position of particles of matter to one another, impossible? It would seem that when a particle of matter bursts into life there would be something approaching absolute contact between elements or perhaps a sort of fusion—an incorporation of the non-living by the living. If this be so the idea of life being in any way derived from non-living can only be entertained by doing violence to reason in submitting to authority. It is by submission to authority only that anyone who thinks over the facts can look into a living organism and assert that it is like a machine he is able to make; that our tissues and organs by which we work, our very thoughts, are due to anything like a mechanism the various parts of which have been first made and afterwards fitted together before they begin to work. The body may be called a molecular complex machine for the transformation of energy—a laboratory without apparatus—without a chemist; and death regarded as a breaking down—a disintegration of the several parts of the machinery, but there is not a shadow of foundation in fact for such a doctrine.

The idea, then, of one single separate living particle is, I think, untenable, for it involves an unknown centre and unknown circumference—multitudes of particles or parts in constant motion, frequent contact, never-ceasing change while the living state lasts—particles of different sizes, different constitution, of different ages.

There is no evidence as far as I can ascertain in support of the proposition that vital power was directly or indirectly derived from anything upon or in the earth, water, or air. Nor has it been shown that at the death of any particle of bioplasm its vital power is resolved or changed into anything that belongs to a category in which matter, its forces or properties, can be included. Nor, I believe, has it been suggested that if life had never appeared on the earth the vast non-vital cosmic phenomena would have been widely different from what they are and have been, or that sun, planets, or other heavenly bodies at a distance from us would have been in any way different from what they appear to be. In short, that however many millions of ages we may postulate, no adequate reasons can be advanced in favour of the doctrine that the living has been derived from the non-living or that the living is in any way an outcome of the cosmos necessary or accidental. There seems to be no connexion between the state of our material world previously to the appearance of life and living nature.

I do not believe that anyone who has studied and pondered over the mere movements he has seen in clear, structureless, colourless bioplasm, to say nothing of the manner in which various kinds of formed material are, as it were, laid down by it, will dismiss these life movements from his mind, as examples of ordinary molecular or undulating movements, and tissue formation as an instance of accretion or aggregation or deposition from a fluid; for between such physical processes and growth there is a vital difference. Does not philosophy, and more than philosophy, separate all living from all non-living?

I feel grieved to think that one who has undoubtedly taught more of us to think than all other writers and thinkers of our time, and whose great intellectual achievements as well as his philosophical and systematic arrangement has benefited all thoughtful students of natural knowledge, should have adopted the views he enunciated in his chapter on Life. I have often desired to discuss with one of Mr. Herbert Spencer's disciples the facts and arguments advanced, but so far no opportunity of doing so has offered. The objections which must have occurred to many biologists appear not to have been considered. The doctrine is undoubtedly inconsistent with many facts of living nature and I do not believe it can be successfully defended in accordance with reason.

For long, indeed, have I been hoping to see some further developments and explanations of Mr. Herbert Spencer's views concerning Life, or at least articles in defence of his doctrines[1]; but, as far as I know, not a word of explanation or any expression of doubt, or promise of reconsideration has been vouchsafed—not an admission of the least possibility of his views upon life being inconsistent with actual vital phenomena, nor a suggestion as to the meaning or explanation of the real nature of what all may see in the microscope as now demonstrated in every course of biology.

Growth is certainly not in any way a modification of the process which occurs when carbon accumulates on the wick of an unsnuffed candle. This is not *growth*, and I maintain that there is no "community of nature between organic and inorganic growth," as affirmed by Mr. Herbert Spencer. *Growth* implies much that Mr. Herbert Spencer ignores, and, as I have often pointed out, he uses the word *growth* in two totally different senses ("Protoplasm," p. 154). Crystals do not *grow* as living matter *grows*, and as all living things grow. The processes are absolutely distinct and the "*growth*" of living things implies Life, and such growth never occurs in the absence of life.

Microscopical work with high powers.—When I began to work with the microscope like my teachers Todd, Bowman, and George Johnson, I seldom appealed to powers magnifying more than 250 diameters, but before long I found there was much more to be discovered in the minute arrangements of some of the simplest tissues than I could demonstrate with that degree of magnifying power, and I obtained from Powell and Lealand powers of about 500 and 700 diameters. As the plan of preparation of specimens became more perfect, new demands for successfully examining them arose, and about 1855 several $\frac{1}{16}$ths of good defining power were produced, and in 1860 they made for me a $\frac{1}{25}$th, by the aid of which glass several drawings of animal tissues were made and published in various memoirs between 1862 and 1870. In 1864 the same makers succeeded in giving me the advantage of $\frac{1}{50}$, which magnified nearly 3000 diameters. The "thin glass" difficulty was overcome and one soon became able to clean the glasses, mount the specimens and with care as regards illumination get some drawings on wood blocks for illustrating my investigations.

About this time my ardour was somewhat damped by the little notice German observers took of my work—a line or so and my name seemed to be all that the most distinguished

[1] See "Protoplasm," fourth edition, p. 143, *et seq*

Digitized by Google

mong the minute anatomists considered I deserved, even before 1870, and since that date, perhaps because I became professor of medicine and was engaged in practice as a physician, some of my German anatomical friends seem to have regarded me as an extinct observer—a fossil.

A few months ago, however, I was delighted to receive from my old friend, Professor Dr. Albert v. Kölliker, his memoir, "Die Energiden von v. Sachs im Lichte der Gewebelehre der Thiere," in which to my "Germinal Matter (Bioplasm) and Formed Material"[2] have been assigned what I cannot but regard as pleasant places among the results of the labours of those for whom all observers have the highest respect and regard. Soon my spirits rose, my vitality improved, and some of the most important of my tissues seemed to regain some of their old elasticity. "Bindegewebe" and "Intercellular-Substanz" excite in me fresh emotions, and I almost long for further friendly contention as to their nature and origin, while I cannot for long resist the temptation of again attacking from my point of view the structure of the outer part of the cerebral convolutions. I hope some rising observers will at least contest with me the fundamental question of the central and peripheral general distribution of nerve fibres, say, for preference, in the little hyla, but I am equally ready for the investigation to be on the bat's wing, the white mouse, or on man himself. Nerve distribution just beneath mucous membrane, or to striped or unstriped muscle (mylohyoid muscle, bladder of the frog, are advantageous for the purpose). Any microscope, any power, any illumination, any method of preparation. I press my conclusion as to there being "no ends of nerves, and the continuity of a nerve fibre to and from its central origin, and peripheral distribution"; my specimens forcing me to this conclusion and, in my judgment, rendering no other inference probable.

Bioplasm undoubtedly receives and transmits impressions from without and from within and by continuous nerve fibres are nerve currents conducted to and fro. Nerves and nerve centres could not exist and could not have been formed but for their connexion with bioplasm or living matter.

With the utmost advantages I could obtain as regards illumination, the best object-glasses, and the most careful preparation of specimens for special examination with high powers, I could not get any farther towards the solution of the constitution of the bioplasm; and whatever may be done in later times I feel confident that no means yet discovered will enable us to make out any structural arrangement which will afford us a correct idea of the manner in which the colourless, structureless bioplasm effects the changes which are undoubtedly somehow achieved by it. Nor do I believe that if the living matter could be magnified many thousand diameters we should see more or learn more concerning this inner life of bioplasm.

In truth, so far I feel as regards the investigation of the ultimate constituents of living matter doubts and difficulties somewhat similar to those which astronomers experience in endeavouring to form an estimate of the contents of the universe. "We are to reflect that all objects which we can see constitute in all probability not one-thousandth, perhaps not one-millionth, part of the material heavens."[3]

However, as it seems not improbable that some new kind of glass may be discovered superior to any now used for optical instruments, and particularly for high-power objectives, great advantage may be gained as regards successful investigation of which at this time no idea can be formed.

It may surely be a question how far scientific workers are bound to obey scientific authorities or any authorities supposed to be supported by being placed at the head of those who work at science, whether superiors, equals, or inferiors. Few men who have long studied and worked hard simply because they loved to learn, to satisfy a right curiosity, a craving to know, will feel inclined to bow to dictators of any kind, not even if backed by what is called public opinion or a general consensus in favour of a particular view. Though scientific work and original thought may have a tendency to make men rebellious, of all tyrants a scientific tyrant may be not the least inconsistent, the least arbitrary, the least unreasonable, or the least inconsiderate.

Undoubtedly for a long time certain scientific men have been permitted and encouraged by the public to wield authority and have been generally spoken of as "authorities." But in science there is no authority (except reason). Some of these "authorities" have done their best in England to enforce the acceptance by the public of certain mechanico-chemical doctrines of life, and some of them have professed to be able to account for vital phenomena by the properties, actions, and interactions of ordinary matter. Undoubtedly any authority can prevent, destroy, degrade, ill-use, or kill in an instant, what it may seize among the living things it calls mechanisms, but he is as absolutely incapable of making, forming, causing to be evolved, the smallest particle of anything like the living matter of the meanest and lowest of the numberless living organisms around, as he is of influencing in the slightest degree the mighty phenomena of suns and worlds.

I challenge those who still insist that life is a form of, or in some way due to, physical and chemical change only to consider the changes of bioplasm and then to bring forward the evidence upon which their conclusion is based and also the facts upon which they rely to disprove the existence of vitality as a factor, a power distinct and not in any way emanating from, or originating in, ordinary matter, its forces, properties, or activities. Nay, I believe them to be unable to show that at this time any evidence justifies us in inclining ever so slightly in the direction they indicate, as to accept the notion that in some distant time the physico-chemical doctrine of life may perhaps be established. I challenge them to reasonably account for the facts of the simplest vital actions in the absence of some directing arranging selective agency unknown to science.

Who will prove that the *growth* of any living particle of any living thing in nature, its power of movement, its power of transmitting to matter, its analytical, its constructing, its formative capacity, depends upon any chemico-physical or other material properties or characteristics of any form of non-living matter known to science or likely to be discovered? Surely we might as well essay to discover good and evil, love and hate, truth and its opposite, or right and wrong in machines, in chemical compounds, crystals, or atoms, as to teach that the living and non-living are one.

The question is of universal interest and, in my opinion, so very important that it deserves much more consideration and thought than has yet been accorded to it, especially in its bearing upon our highest hopes and interests.

As biology is now receiving much more attention than heretofore and in all probability will soon be one of the subjects of general education and taught in most schools, teachers can hardly avoid referring to living and non-living, to life and death. I naturally feel anxious that the conclusions I have adverted to should now be submitted to the judgment of the thinkers and careful observers of our time, and I hope if my views should fall under the notice of observers and fellow workers in other parts of the world, particularly in America, Australia, and of microscopists of India and Japan, they will consider my views and publish facts adverse or favourable, as the case may be, but first from the observation side. To go into the general bearing will be premature until the question of Vitality is affirmatively answered, or again has to be dismissed as unscientific or impossible.

To the Editors of THE LANCET I feel greatly indebted for allowing me to bring these views before my brother practitioners and I hope that the following summary may be brought under the notice of readers likely to be interested by the editors of other journals.

A reprint will shortly be published by Messrs. J. & A. Churchill, 7, New Burlington-street.

CONCLUSION.

In conclusion, then, I shall venture to repeat that as far as I am able to judge the evidence to be adduced at this time in support of the view of the absolute separation of living from non-living matter is conclusive. The gulf between them has not been bridged or filled up and there is no sound reason for thinking that it will not for ever remain as wide and as deep as it is.

So, too, from life to death the change is absolute as regards any actual living particle. It seems to me there is no gradual or progressing change. Matter is either living or not living. It does not gradually pass from one state into the other. There is no half-life or half-death in the case of a definite particle or portion of bioplasm.

The exact seat of the operation of vitality—the exact matter which possesses vital power—has been determined

[2] Die Structur der einfachen Gewebe des Menschlichen Körpers. Translated by Professor Victor Carus. Leipzig, 1862.

and pointed out in various living forms differing widely from one another. In what respects the matter which is the temporary seat of vital action—the bioplasm, which may undergo conversion into tissues and various other formed matters—absolutely differs from these as well as from products resulting from metabolic change has also been indicated.

The structural peculiarities of all tissues and the properties and chemical composition of many formed matters produced in living organisms I attribute to vitality. Further, the evidence which has convinced me that this vitality actually overcomes, but in some way we do not understand, the ordinary forces and properties of certain kinds of non-living matter is in my opinion conclusive. Certainly parts of a particle of living matter are during life placed, or place themselves, above other portions—in fact, over, under, or on either side, and, indeed, in any position, with equal facility. The matter may move in any direction and portions may move *into* and mingle with one another.

As far as can be ascertained Vital Power, Vitality, Biokraft, can only be conferred upon matter in one way by vital power always derived from already existing living matter.

Associated with vital movement and the other usual but inexplicable endowments of living matter we must not forget that in particular instances we have in addition the evolution of heat, light, and electricity, and perhaps other forms of energy,—but how the conversion of energy is effected by the bioplasm is still a mystery. It is difficult to see how, by denominating a specimen of soft, moist, structureless, colourless substance, a molecular mechanism or machine, or by speaking of it as an apparatus or a physical or chemical laboratory, anyone can help us to discover a solution of the mystery.

Every kind of living matter in nature, whatever may be the results or consequences of its living, whatever may be the characters, state, or properties of the particular particles to which vital power is about to be communicated, the matter in question is always associated with a very large proportion of water, and probably in all cases the matter about to live is actually dissolved before any vital change occurs.

Bioplasm is invariably devoid of form, colour, structure, at the moment of its production—characters which in all things living have been brought about by the influence of Vitality. In fact, colour, form, and structure are not manifest until all vital power has ceased to influence the matter. The results as regards these qualities vary according to the special powers with which the living matter was endowed and these were all derived from pre-existing living matter.

This *vital power*, this *vitality* in which I have been led to believe, exists in connexion with every form of living matter, it never undergoes conversion into any form of energy or, as far as can be ascertained, into anything else. It may cease at any moment and if it governs the changes which indicate that it is a transformer of energy, certainly so far, science has failed to establish even a probability that vitality itself can be transformed in any definite way. *Vitality* may direct, govern, rearrange, determine the movements of atoms or particles of matter. It has not been proved that vitality can act even through the least distance or in any way affect or influence particles to be made to live, separated from those that live by the very slightest interval. Matter to be made living must be infinitely near or perhaps must pass into the very substance of matter which already lives.

The very existence of vital power has been affirmed, denied, and re-affirmed over and over again, but a correct estimate of conclusions advanced by different investigators in the pre-Victorian age can hardly now be formed because in those days the means of examination of the various tissues and of the living matter by high magnifying powers was not possible. The general nature and origin of living matter had not been investigated—in fact, only during the last few decades have we been able to study the movements of various forms of bioplasm and trace the formation of tissues through the several stages of their development with the aid of high magnifying powers and much improved methods of preparation.

The beginning of the world of life—*our world of life*—was surely a very different beginning—a beginning of a nature, order, or kind different indeed from the beginning of any material world—of any lifeless cosmos—of the universe; and could not have occurred until immeasurable periods of varying conditions of matter all absolutely destitute of life had passed.

It is surely impossible to believe now that life of any kind was either an accident, a necessity, or a certain and necessary consequence of any material forces, actions, or influences which preceded its appearance; or that the first indications of the presence of life upon the earth could have been occasioned by any ordinary changes in matter or its properties, no matter how many æons may be allowed for the "working hypothesis" of creation. There seems no adequate reason for suggesting that some special or exceptional state or condition of the surface of our earth or its waters that preceded gradually led to the evolution of life and living nature, from non-life. Gradational or very pronounced divergencies from, or approximations towards, particular types, as may be suggested in certain cases, seem to have been transitory and in some instances to have disappeared. No reasonable explanation of the early changes or of the advent of contemporary forms differing widely from one another in structure and in vital powers seems yet to have been arrived at.

I earnestly appeal to all interested in this comprehensive and most important question, and beg them to consider whether the evidence adduced in favour of vitality is not justified by the facts and arguments brought forward—evidence of a wide and general character, as well as evidence derived from minute investigations in many organisms, general microscope evidence, and evidence from demonstration with the aid of very high powers of specimens from all kinds of tissues and organs.

All interested in the advance of natural knowledge will desire for instance that questions bearing upon the nature of nerve action and mind should be carefully considered from all sides, and that facts and arguments for and against given views should be thoroughly examined and sifted. Of these not a few have been accumulating during the last half century.

Must we not admit the constant operation in all living matter, bioplasm, of a power absolutely different from all forces, properties, energies, activities, principles that are known to belong to any form of non-living matter? I beg to challenge those who take the contrary view and meet this question of vitality with a direct negative to plainly state the grounds of their objection, and to explain how according to their views life facts, movements, origin, growth, production of structure—in short, how life and death are to be accounted for.

I hold that there is no evidence in favour of the doctrine that by the science of the future this vital power, this vitality, will be proved to have sprung from, or to have been in any way at any time connected with, to have belonged to or to have emanated from, ordinary matter, or the opinion that it has been communicated to anything non-living through the intervention of matter or agencies of any kind except the actually living.

And I submit that if all life were to cease in any part of our world it could reappear only by the re-importation, the re-introduction, of bioplasm that already lives, and that it is certain that a living thing—a living particle—that has once ceased to live cannot be restored to life. The same living particle once dead does not regain its life, though the substances formed at its death may be taken up by other kinds of living matter and some of their constituents converted into that particular kind of bioplasm.

To this influence of vital power—vitality—biokraft must, in my judgment, be referred the millions of forms, structures, and actions which characterise the living world and enable us to identify and name each different organism that now lives or that has lived in past time of which any imperishable remains have been discovered. Ever since vitality was first conferred upon certain kinds of matter there is reason to believe that vital action has proceeded upon precisely the same lines as obtain in our living world of to-day.

I cannot suppose a minute particle of living matter which does not consist of particles still more minute. In each particle there seems to be a general movement proceeding in a direction *from* centres. The new substances introduced acquire the living state in these centres. In consequence of the vital movements *from* centre, *centrifugal*,—currents of fluid holding in solution nutrient matters are produced in the opposite direction—*centripetal*. Here, where no eye has yet penetrated, the non-living becomes living, possibly according to the operation of some vital laws, but somehow independently of, and removed from, the operation or influence of laws physical and chemical.

According to law an apple fell, but are we never to be

Digitized by Google

permitted to consider and inquire how the scaffold rose before the fall, and to remember that in their fall dying and dead apples drag with them to the ground many a new vitality from which stems and leaves, and flowers innumerable, and bounteous fruit, may spring and grow in all their glory, to benefit and delight the thinkers and workers of another age, who will think over and learn ever more and more about the life and growth and death of living things which may then be alive, as well as of those that lived and died in the ages long ago?

I claim, then, for all living nature a position of its own, apart from all non-living and maintain that this conclusion is proved by facts of actual observation, and is in accordance with reason. In short, I claim upon rational and scientific grounds for *Life*, for *Vitality* as manifested by all living nature, the whole living world, by everything that lives and that has lived,—absolute distinction from all non-living, on account of differences in essential nature, differences as regards the principles of *origin*, *multiplication*, *growth* and *action*, and in the manner in which life is influenced by external circumstances. So far from obeying laws by which the material universe is governed, Vitality seems to overcome, during the time of its operation, the influence of physical law. The laws of the living world, if laws there be, belong to an order or category different and apart from that in which physical law is included. The laws of matter and energy are not the laws of life. While matter lives the ordinary properties of the matter seem to be in abeyance and cannot be made evident. Can it be said of any form of vital power that it is indestructible like matter and energy?

From the first moment of existence of an individual organism, as an exceedingly minute living germ, to the production and death of the millions of bioplasts in descent from it, life might easily have ceased at any stage, at any moment, never to return. I claim for *Biology*, *the Science of Life*, its rightful place among the natural sciences, and a place in natural knowledge equal to that accorded to physiology, natural history, zoology, botany, though biology comes last in time. And for *Bios*, *Life*, *Vitality*, *Biokraft*, a place as far above all cosmic matter, its forces and properties, as the imprints of living things and thoughts we alone can understand, are above the passive stuff we make and mould and fashion as we design and will.

Do not even machines, appliances, structures, arrangements, and all the works we plan and make and cause to work, as well as the wonderful records of the past left by man and only to be read by his descendants, infinitely transcend the limits within which all forms and states of cosmic matter, with its energies, activities, properties, potentialities, physical and chemical phenomena, laws and orders, are, have been, and must ever be confined?

My earnest belief is that the evidence I have adduced in proof of the view that all life and living things are, and have ever been, absolutely marked off from all non-living is convincing and incontrovertible. There is, however, very much more to be said concerning this great problem, particularly as regards the wide general bearing and application of my views on the nature of vitality. But how far and for how long existing scientific authority and our reviewers who rule us all—and with a rod of iron—will permit me to go on I cannot tell.

'O *Bios Βραχύς*.

THE VALUE OF OXYGEN IN POISONING BY MORPHINE.

BY DAVID T. PLAYFAIR, M.D., C.M. EDIN.,
MEDICAL OFFICER TO BROMLEY COLLEGE; HONORARY MEDICAL OFFICER TO BROMLEY COTTAGE HOSPITAL.

THE following case of morphine poisoning cannot, I think, fail to be of much interest on account of the almost miraculous recovery the patient made after an enormous dose of the toxin and when death seemed certainly inevitable. Before entering into the details of the case I wish to say that if it had not been for the most kind, able, and energetic coöperation of my partner Dr. Scott and my friends Dr. Chatterton and Dr. Ilott the treatment could not have been carried out to its satisfactory termination. To them my sincere thanks are due.

The patient was a woman, aged thirty-seven years, healthy and of excellent physique. Her early breakfast was brought to her in bed as usual at 7.15 one morning this summer. She then appeared to be perfectly well and spoke cheerfully to the maid who attended on her. About 9.45 A.M. she was observed to be sleeping soundly and at 10.30 A.M. a friend finding her still asleep mentioned the circumstance to the lady of the house, who at once went to see why her guest had not risen. The appearances the latter presented immediately roused her suspicion that there was something wrong and she promptly summoned Dr. Scott, who happened to be not far off. On his arrival at 10.40 A.M. he at once diagnosed opium poisoning and on search being made it was discovered that a bottle in one of her toilet-table drawers—known to have held over two-thirds of an ounce of injectio morphinæ hypodermica, British Pharmacopœia 1885, thus containing over 30 grains of morphine acetate—was empty. The following were the appearances noted by Dr. Scott when he first saw the patient. She was lying on her back in a comatose state from which it was impossible to rouse her, although the interrupted current when applied to certain parts caused some slight muscular contraction and the conjunctival reflex was not absolutely lost. The face was livid almost to complete greyness and the fingers were ashy-grey as far as the second joints. The pupils were contracted and did not react to light, but neither then nor afterwards were they strikingly small or "pin-point." The breathing was very slow and shallow, not stertorous. The pulse was slow and fairly strong and muscular relaxation was complete. This condition very quickly passed into the most profound coma and the pulse rapidly got weaker. Steps towards resuscitation were immediately taken. While an œsophageal tube was got ready ether was hypodermically injected and the faradaic current was applied. With the assistance of Dr. Chatterton and Dr. Ilott, who had been sent for, the tube was passed into the stomach and that organ was thoroughly washed out first with water and then with a solution of permanganate of potash, a pint of strong coffee with 1 oz. of brandy being afterwards introduced. Before this had been completed faradaism was discontinued as it had failed to elicit any response. It was noticed that while the stomach was being washed out the breathing deepened and the colour became less livid, but soon after the completion of this operation the lividity returned and the breathing became more and more shallow and slow till it finally ceased altogether at 11.30 A.M. Two hypodermic injections of atropine with $\frac{1}{100}$th of a grain of strychnine had already been given and these were followed at intervals by two others of $\frac{1}{100}$th of a grain of atropine. A cylinder of oxygen had been sent for. Cyanosis was now intense and the pulse was exceedingly feeble. Artificial respiration, which had been begun, produced little or no alteration of colour or pulse. At 12.30 P.M. an enema of strong coffee and brandy was given and mustard was applied over the cardiac region and to the feet. Artificial respiration was steadily persevered with and at about 12.45 P.M. the inhalation of oxygen was commenced. In a very short time this rendered the cyanosis much less marked and distinctly strengthened the pulse. At 2.40 P.M. an enema of hot bovril was given. At 3.20 P.M. the condition was unaltered save that the pupils were widely dilated. There was still no indication of natural breathing. Another $\frac{1}{100}$th of a grain of strychnine was now injected and frequent injections of ether were kept up. At 4.20 P.M. 1 oz. of brandy was passed into the stomach. At 5 P.M. the patient's condition seemed utterly hopeless. There had been no sign of natural breathing for about five and a half hours, the pulse was getting much weaker and the cyanosis became intense if the oxygen were stopped. Some improvement, however, set in shortly after this and at about 6 P.M. the patient began to make an occasional slight inspiratory effort—about one exceedingly feeble gasp per minute—and the colour became lighter. At 7 P.M., however, the end again seemed to have come and we expected death to occur at any moment. Still the pulse could be detected and the treatment was uninterruptedly carried on. Half an hour later (at 7.30 P.M.) indications of respiration of Cheyne-Stokes character began to show themselves at intervals and the colour had much improved. At 8.10 P.M., very slow, shallow breathing having commenced, artificial respiration was stopped for twenty-five minutes, oxygen still being continued. At 8.35 P.M. natural breathing again threatened to

Digitized by Google

cease and for five minutes artificial respiration was resorted to, a period of twenty-eight minutes of natural breathing following, at about 12 per minute. Again this ceased and artificial respiration was resumed for twenty minutes. At 9.50 P.M. natural breathing seemed tolerably established, though it was still of the Cheyne-Stokes type. The colour for the last hour or more had been decidedly improving, there being now distinct redness of the lips and cheeks. Application of the interrupted current at this period caused very considerable muscular contraction. At 10 P.M. the oxygen was stopped. The pupils were not so dilated and reacted slightly to light. At 10.15 P.M., the pulse again failing and lividity returning, oxygen was given for five minutes, the colour and pulse promptly improving. At 10.40 P.M., to our astonishment, she opened her eyes and spoke in answer to questions and at 10.50 P.M. she swallowed some black coffee. For two hours after this she could not be got to speak again, though on faradaisation she roused herself, moved her position in bed and looked about her, her colour and pulse keeping good. At 1 A.M. she again answered when spoken to and from that time to 3 A.M., when we left her in chargo of two nurses, she was conscious though dazed and drowsy. Shortly after 9 A.M. I again saw her and found her sitting up in bed and enjoying a breakfast of coffee, bread and butter and complaining of nothing save a bruised feeling about the chest and arms, doubtless due to our efforts in keeping up artificial respiration so long.

Among the remedies given a trial in the earlier part of the day were ammonia and amyl nitrite, but these seemed as useless as the others employed. Nothing but oxygen was apparently of any value. During the whole time good bodily heat was maintained and there was little or no diaphoresis and no vomiting occurred.

Cases of recovery after a larger dose than 30 gr. of a morphine salt have been reported. I am unable, however, to find more than the mere statement of this fact and I am unaware in any such instance how long the poison had been taken before treatment was commenced. A recovery such as in the present case, when so large a quantity was taken on an empty stomach, the patient's condition remaining undiscovered till more than three hours afterwards, must be exceedingly rare. My object in reporting the case is to add my experience of the immense therapeutic value of oxygen in opium or morphine poisoning to that of those who have already advocated its use, and to urge its employment in such cases. Most certainly without its aid my patient would have died. In THE LANCET of June 2nd, 1894, Dr. W. J. C. Merry noted a case where it proved of great value after 2 oz. of chlorodyne (containing probably about 8 gr. of morphine) had been taken, and Dr. C. J. Macalister in THE LANCET of Dec. 7th, 1895, details another instance where it was found of much service after eight pills, each containing ½ gr. of morphine, had been swallowed.

Fortunately for my patient supplies of the gas were able to be obtained without much delay. Artificial respiration by Silvester's method without oxygen quite failed to remove the intense cyanosis or to strengthen the pulse. The gas was administered by passing into the mouth a vulcanite nozzle attached to a tube leading from the cylinder, an india-rubber regulating bag intervening. At each inspiratory movement a stream of gas was allowed to flow, the tube being pinched close during the expiratory movement. This was kept up with the exception of the two intervals of natural breathing I have mentioned for about nine and a half hours. Altogether about 80 cubic feet of oxygen were used. During the very short intervals when the supply was stopped on account of a change of cylinder or when the œsophageal tube was passed the lividity rapidly deepened and the pulse as rapidly got weaker. In about half a minute after resuming the oxygen marked improvement took place as regards colour and strength of pulse.

I am much inclined to agree with the idea that oxygen not only acts as a heart stimulant but possesses some direct oxidizing effect on the poison. Considering the amount of morphine swallowed, the comparatively short time (ten hours) that elapsed between the commencement of the inhalation and restoration to semi-consciousness seems to me to indicate that some chemical change must have taken place by which much of the activity of the poison which had been absorbed had been destroyed.

In conclusion, I may say that my patient has never been addicted to the misuse of drugs and has never required to take any form of narcotic on any occasion.

THE ACTION OF THYROID AND PARATHYROID EXTRACTS UPON METABOLISM IN THE INSANE.[1]

BY C. C. EASTERBROOK, M.A., M.B., C.M. EDIN.,
ASSISTANT PHYSICIAN, THE ROYAL ASYLUM, MORNINGSIDE, EDINBURGH.

DURING the past two years the experimental work more particularly of Vassale and Generali in Italy, of Gley in France, of Blumreich and Jacoby in Germany, and of Welsh in this country, has drawn attention to the probable importance of the parathyroid bodies in the economy. Until recently most of us believed that removal of the thyroid gland is followed by characteristic symptoms, although even amongst the thyroidectomists there are some (e.g., H. Munk) who attribute the effects produced not to the removal of the gland substance but to an interference with adjacent nerve structures in the neck involved by the operation. More recently, however, the parathyroidectomists have appeared on the field, and although they are still a divided camp some of them (e.g., Blumreich and Jacoby) holding that one and all of the parathyroids may be removed without ill effects, the majority of them maintain that their experiments favour the view that the time-honoured acute effects of thyroidectomy are to be attributed to the removal of the parathyroids alone. The experimental removal of the thyroid and parathyroids has thus led to very conflicting views, and the work of the more recent parathyroidectomists would suggest that the parathyroids are physiologically more important than the thyroid and that possibly the activities of thyroid preparations might be due to an admixture of parathyroid. It therefore occurred to me that light might be thrown upon the matter from the pharmacological side by the administration of parathyroid extracts, which, so far as I am aware, have not previously been exhibited in the human subject. One would thus be able to compare the effects produced with those which occur during thyroid administration. Within the limits of this paper it will only be possible to consider the pharmacology of the thyroid and parathyroids; their therapeutics will not be referred to.

The patients to whom these extracts were administered were women suffering from insanity, either chronic and incurable or threatening to become so. Each patient was weighed, kept at rest in bed, and put upon a fixed mixed diet sufficient to maintain the body-weight and body temperature. By rest in bed one controlled more particularly non-nitrogenous metabolism and the excretion of carbonic acid and water. By maintaining a "fixed mixed diet" one controlled more particularly nitrogenous metabolism and the excretion of urea. We know that the food necessary for the life and work of the body must contain in suitable quantities proteids, carbohydrates, fats, salts and water; that the water and salts are largely eliminated unchanged, that the fats and carbohydrates are completely oxidised and escape as carbonic acid and water, and that the proteids, which alone enter into the formation of the living tissue or bioplasm of the body, are incompletely oxidised, two-thirds of every proteid molecule being excreted as carbonic acid, water, phosphate, and sulphate, and one-third escaping as urea. It is thus possible to gauge the metabolism of the body by controlling its food and work and by observing its elimination of water, carbonic acid, urea, and other metabolic products. When a patient is kept at rest in bed and upon a fixed mixed diet, metabolism "strikes a balance" which it is possible to upset by the introduction of drugs into the system. In the course of a few days, by which time the patient's metabolism under the conditions of rest and diet had become stable, a careful note was made of the state of the various bodily functions and organs, including investigations of the pulse, blood, and urine, and the drug was then commenced. During its administration periodical examinations were made as before. The drug was stopped in due course and a few days later the examinations were repeated for the last time, the patient was weighed, and finally she was allowed to be up and about and to return to ordinary diet and modes of living.

PARATHYROID EXTRACT.

The parathyroids of the ox were selected, this being the most convenient animal from which to obtain a sufficient supply of these small bodies. Dr. Welsh of Edinburgh, who has recently given an excellent account of the anatomy of the parathyroids in man and of the effects of their removal in cats, was kind enough in the first instance to make me familiar with their appearance in the ox. In order to avoid any risk of removing thyroid tissue along with the parathyroids I employed only the external parathyroids, these being anatomically separate from the thyroid and not, like the internal bodies, incorporated with the larger gland. The external parathyroids of the ox lie one on each side just under cover of the free dorsal borders of the lateral lobes of the thyroid opposite about the lower level of the isthmus. They occupy the stratum of fat which separates the thyroid lobe ventrally from the pharynx-œsophagus dorsally. Not infrequently they are blended with islets of thymus tissue. They are usually somewhat flattened and pyriform, the sharp end, directed towards the middle line, being continuous with a stalk or pedicle which contains the blood-vessels and penetrates the deep surface of the thyroid. They measure from ¼ in. to ½ in. in length and weigh from ½ gr. to 1 gr. They have a smooth surface and a reddish-brown colour, and their cut surface is relatively dry and lacks the juicy appearance of freshly-cut thyroid tissue. Microscopically they consist of closely-packed groups or columns of cubical epithelial cells, with a delicate intervening stroma, and in places there is an appearance of a lumen in which there is sometimes colloid-like material. The parathyroids of the ox, like those in man, may thus exhibit what Welsh describes as the more highly specialised types of structure. The chemistry of the parathyroids is unknown.

In my first case of parathyroid treatment I commenced the drug on the fifth day of rest in bed with fixed diet. In the first instance the fresh glands were dried for twenty-four hours in a sulphuric acid chamber and administered by the mouth. In this way 1 dried gland was given by the mouth every morning for a week (fifth to eleventh days), 2 dried glands were given on the twelfth and thirteenth days, and 3 on the fourteenth day. No effects were observable. On the fifteenth and again on the sixteenth day 3 glands, dissected the same morning, were administered straight away in the fresh state by the mouth but without any apparent change in temperature, pulse, respirations, urine, or in metabolism generally. As mouth administration gave negative results, hypodermic injections were tried after an interval of three days (seventeenth to twenty-first). Extracts in glycerine were used and in this form 1 gland was given on the twenty-second day, 2 were given on the twenty-third and twenty-fourth days, and 3 on the twenty-fifth day. During the treatment by subcutaneous injections of glycerine extracts the patient was kept under careful observation, the temperature being taken every hour day and night. The only changes noticed were (1) a slight diminution in the red blood corpuscles; this quite probably was due to the interference with the patient's sleep involved by the taking of the temperature; (2) a slight increase in the predicrotic wave of the pulse-curve. A rise in pulse-tension, however, has been frequently observed to follow the subcutaneous injection of other animal extracts, so that one was not justified in inferring that this was a specific action of parathyroid extract. In my second case extracts were made in glycerine, in sulphuric ether, and in 10 per cent. sodium chloride solution. They were injected subcutaneously, the doses in the case of each extract being equivalent to from one to four fresh glands. The results were again negative, though the treatment was persisted in for seven weeks. In this case the glycerine extracts produced no diminution of red blood corpuscles, the ethereal extracts produced a transient quickening of the pulse apparently due to the ether, and the saline extracts produced no effect at all. In a third case glycerine extracts were given hypodermically, containing in each daily dose as much as nine fresh glands—that is, more parathyroid than would be found associated with two thyroid glands in the whole animal. No change occurred in temperature, pulse, or respirations; there was no increase in the output of water and carbonic acid; there was no change in the urinary nitrogen and phosphoric acid (which were estimated daily); and, in short, the patient exhibited none of the constitutional effects of thyroid feeding, but, on the contrary, she actually gained 2lb. in weight during the treatment. After a few days' interval she received thyroid treatment by the stomach in doses equivalent to one fresh thyroid daily and she at once exhibited the effects of the drug in a marked degree and lost 10lb. in weight in a week. This case proves conclusively that in a patient actively susceptible to thyroid, parathyroid, even in relatively larger doses, produces no effects comparable to those which occur during thyroid administration. And indeed, in my hands the external parathyroids of the ox when administered to the human subject, whether in the solid state (dry or fresh) by the mouth or in the form of glycerine, ethereal, or saline injections under the skin, seem to produce no effects at all except a slight increase in pulse-tension in common with various other organic extracts.

THYROID EXTRACT.

It is now established that the essential active principle of the thyroid gland is Roos and Baumann's thyroidin, which seems to be identical with the active constituent of R. Hutchison's colloid powder ("thyrocol"). I have been unable to obtain pure thyroidin for therapeutical purposes, but in 10 cases I have used "thyrocol" and in 85 cases the more familiar thyroid tabloids or dry extract of the gland. The actions of thyrocol I found to be the same as those of the tabloids, and the toxic and undesirable effects upon heart, stomach, and nervous system occurred equally with the one as with the other and are due, in my opinion, to the thyroidin contained in the preparation and not to the accompanying "useless" proteid and extractive matters. The sheep's thyroid contains on an average from 0·2 per cent. to 0·5 per cent. of thyroidin; this means that one gland may be twice as active as another. An average sheep's thyroid yields about 6 gr. (0·4 gramme) of "colloid powder" and about 60 gr. (4 grammes) of "dry extract," or 12 "tabloids." In the majority of the cases I employed, as originally suggested by Dr. Lewis Bruce in his "Thyroid Treatment of Insanity," doses large enough to produce thyroidism. Thyroidism is usually brought about in insane patients by daily doses of 60 gr. (20 gr. three times a day) of the "dry extract" continued for six or seven days; this is equivalent to giving one fresh sheep's thyroid daily for a week. In the case of "thyrocol" I found that daily doses of 15 gr. (5 gr. three times a day) repeated for a week were necessary to produce thyroidism. In some cases larger doses were given—e.g., 18 tabloids a day—and in other cases smaller doses—e.g., 1 tabloid or 3 or 6 tabloids a day. In all the cases the effects produced were the same in kind, but varied in intensity according to the size of the daily dose and the duration of the drug. The body weight was of little account as regards dosage, but the drug was badly tolerated by general paralytic and tuberculous patients, still worse by patients over sixty years of age, and worst of all by fat patients, especially those in whom, as Dr. Byrom Bramwell has pointed out, there was reason to suspect fatty degeneration of the heart.

The outstanding effects in my thyroid cases were as follows:—

1. *Body weight.*—The loss in weight was constant and usually amounted to 7 or 8 lb.—that is, a teaspoonful of dry thyroid extract given daily for a week produced a loss of weight at the rate of 1 lb. a day. This was followed after the drug was stopped by a gain in weight which was not so rapid as the previous loss but frequently exceeded it in amount.

2. *Body temperature.*—Pyrexia was not so constant as the loss in weight, and, indeed, a considerable loss in weight might occur without pyrexia. In 20 per cent. of the cases there was no pyrexia. In 66 per cent. the pyrexia was subfebrile—that is, a rise of from 1° to 2° F. above the previous average temperature of the patient, which in most cases was 1° below normal. Dr. Clouston drew attention thirty years ago to the relatively low temperature in dementia and chronic insanity generally—a fact which probably indicates the sluggishness of metabolism in the chronic insane, especially of their nerve-centres. The pyrexia was slightly febrile (a rise of from 2° to 3° F.) in 10 per cent., and moderately febrile (a rise of from 3° to 4° F.) in the remaining 4 per cent. of the cases. Usually the temperature began to rise on the second day of the administration of the drug, gradually reached its maximum, and began to fall again before the drug was stopped.

3. *Integumentary system.*—Perspiration was usually increased, in most cases giving rise to an increased moist feeling of the skin, but in 30 per cent. of the cases being visibly profuse. This means not only that much more water is lost by the body, but also, as Schierbeck has shown, that a considerable quantity of carbonic acid is lost in the sweat; and in addition, after carefully investigating the point,

Digitized by Google

I am convinced that when the skin breaks into perspiration the urea in the sweat at once increases and no inconsiderable quantity of urea may be eliminated in this way. The skin during thyroidism was flushed from the hyperæmia which usually accompanies sweating; a fine desquamation was not uncommon and very frequently the skin became fresh, clear, and healthy-looking after treatment. The subcutaneous fat was obviously diminished in most cases and, indeed, the combustion of fat during thyroidism is probably the main cause of the loss in weight and the chief source of the increased output of carbonic acid and water.

4. *Locomotory system.*—No clinical changes were exhibited apart from nervous phenomena and an incapacity for physical exertion.

5. *Hæmopoietic system.*—The chief changes noticed in the blood during thyroidism, especially when large doses were used, were a diminution in the hæmoglobin and to a greater extent in the red blood corpuscles. The depreciation in the value or worth of the hæmocytes as regards their hæmoglobin was thus but slight. A slight degree of leucocytosis was not uncommon, and in films stained by Dr. Lovell Gulland's method the blood plates were slightly increased. No obvious changes were detected in the spleen or in the thyroid gland.

6. *Nervous system.*—Sensory symptoms in the form of headaches, pains, tinglings and pricklings in the limbs and body generally were common and usually occurred early. Motor phenomena in the form of tremors of the face, fingers, and limbs also set in early and were accompanied later by weakness and a feeling of great exhaustion. An exaggeration of the tendon reflexes was occasionally seen during the earlier stage of the drug. Some degree of mental excitement was frequently exhibited, varying from quiet talkativeness to noisy scolding, restlessness, and impulsive violence, and later the mental signs were rather those of the irritability of exhaustion. The sleep function was not specially affected except in cases where the sensory disturbances were very pronounced.

7. *Circulatory system.*—Tendencies to palpitation and syncope occurred in a few patients who tolerated the drug badly. The pulse was invariably increased in rate, usually by 40 or 50 beats per minute with large doses. Later the pulse became irregular, weak, and soft and in the majority of cases gave the signal when the drug had to be stopped. The pulse remained fast usually for at least a week afterwards and sometimes for a fortnight or even longer. An acceleration of the heart points to an excessive katabolism of its substance, and the fact that thyroid powerfully promotes the combustion of fat seems to me to explain the risk of cardiac failure in cases of fatty heart under thyroid treatment. There is excessive oxidation and disintegration of the heart-wall. Pulse-tracings showed distinct evidence of diminished tension, the predicrotic wave being diminished and the dicrotic wave increased.

8. *Respiratory system.*—The increase in the respirations during thyroidism was constant and amounted usually to six respirations per minute and not uncommonly to ten. As an increase of even one respiration per minute means 1440 additional respirations in the twenty-four hours, it is obvious that the marked increase in the respirations during thyroid feeding, the patient being at rest in bed, points to a remarkable increase in tissue oxidation and to an exaggerated ingress of oxygen and output of carbonic acid and water.

9. *Alimentary system.*—The thirst was commonly increased and the appetite diminished during thyroidism, but after the treatment the appetite was often prodigious. In about 25 per cent. of the cases the digestion was deranged by the drug, the symptoms being anorexia, furred tongue, nausea, vomiting, and in some cases biliousness and diarrhœa. In my opinion thyroid dyspepsia is due to a local irritation by the active principle of the drug (thyroidin), which, as is well known, is stable enough to resist gastric digestion, and so if supplied in sufficient quantity it will irritate the lining of the stomach, the duodenum, and even the lower bowel. Thyroid dyspepsia is a complication which sometimes necessitates the discontinuance of the drug and it renders observations upon metabolism useless. The action of the bowels was not notably improved by thyroid in my cases, but it will be remembered that amongst insane women constipation is a marked feature and is very intractable. The excretory nitrogen in the fæces was not estimated.

10. *Urino-Generative System.*—Menstruation was frequently more profuse than usual at the regular periods, in a few cases it appeared irregularly during thyroidism, and in one patient, an idiot, aged twenty-one years, with cretinoid features, it appeared for the first time in the patient's life after she had taken one tabloid for three weeks. The urine was carefully investigated, the twenty-four hours' discharge being collected, mixed, and measured and examined fresh the next morning. The daily amount during thyroidism was usually increased, but to some extent it varied inversely with the perspiration. The colour and specific gravity were frequently increased. Turbidity was common. The mucus deposit was not increased as is said to occur in myxœdematous cases under thyroid treatment. The chemical reaction was almost invariably acid but the total acidity was not estimated. Albuminuria was common. Glycosuria was not met with, although sugar was tested for in every case; in all probability the absence of sugar in my cases was due to the fact that the patients were on a fixed diet which did not contain an excess of sugar, for it is the tendency to "alimentary glycosuria" which, according to Bettmann, occurs during thyroid feeding. Uric acid and urates were commonly increased. Bile occurred only in cases in which the digestion was markedly disturbed. The chromogens of indigo-red and urorosein were usually increased. The urine-pigments were not investigated. The total dissolved solids were markedly increased during thyroidism and were estimated in the rough by multiplying the last two figures of the specific gravity by the number of ounces passed in the twenty-four hours. This formula gives the total daily solids in grains. The phosphoric acid was distinctly increased, especially during the earlier stages of the drug; it was estimated by the uranium method. The increase in the phosphoric acid in the urine is probably due mainly to an increased oxidation of the phosphorised constituents or azotised fats—e.g., protagons and lecithins—of the nerve centres. The urinary nitrogen also was much increased, especially in the later stages of thyroidism; it was estimated by the hypobromite method. It must be remembered that the thyroid tabloids consist largely of nucleo-proteids and so are rich in nitrogen and phosphorus, but the amount of proteid supplied in the drug is quite insufficient to account for the increase either of the phosphoric acid or of the nitrogen in the urine.

Conclusions.—The preceding facts show indubitably that thyroid is a profound katabolic stimulant. With the patient at rest in bed and on a fixed mixed diet there is a great increase in all the excreta, especially in the water and carbonic acid and to a less extent in the urea and other products of nitrogeneous metabolism. Thyroid thus greatly accelerates the splitting up and oxidation of the tissues. The fats of the tissues suffer most severely, and the reason is probably simply this—that the fats are the most fluctuating of the tissue substances, they are the most readily formed and the most easily lost of the body stuffs, and consequently when a powerful katabolic stimulant such as thyroid is introduced into the system the fats are the first to be burned up, and when the thyroid becomes eliminated from the system fat is rapidly laid on. Amongst the fats thus affected are probably the so-called "azotised fats," or phosphorised constituents of the central grey matter, and the early excess of phosphoric acid in the urine is probably derived from this source. The tissue carbohydrates are probably also considerably oxidised, and, although the clinical proof of this is not so clear, the great muscular weakness and incapacity for physical exertion during thyroidism may indicate that the glycogen in the muscles, which is the chief immediate source of muscular energy, has been largely burnt up and so is not available. The tissue proteids are also excessively wasted, the "unorganised" proteid being probably affected first and finally the living proteid or bioplasm itself. After the thyroid is eliminated from the system a gain in weight sets in and there are other evidences of a powerful anabolic reaction. The *rationale* of this change seems to me to be explainable by Hering's theory of the "internal self-adjustment of bioplasm," according to which the bioplasm, when it is being katabolised by some stimulus (e.g., thyroid) tends less and less towards katabolism and more and more towards anabolism which sets in with a rebound as soon as the katabolic stimulus is removed.

As to the channels by which the thyroid reaches the tissues, the changes in the blood during thyroidism probably indicate that the drug is distributed by the blood to the tissues, but at the same time the early occurrence of the sensory motor and mental phenomena during thyroidism, the evidences of hyper-activity of the central grey matter followed by the signs of its exhaustion, and the early increase of the

Digitized by Google

phosphoric acid in the urine, all seem to me to indicate that the thyroid specifically stimulates the central nervous system and through it the metabolism of the tissues. In direct support of this view I may mention that I fed two rats upon porridge and water but to one of them was also given daily one thyroid tabloid. The thyroidised rat died with tremors and other nervous symptoms on the fourth day, and while the brain cells of the healthy rat were normal in appearance those of the thyroidised rat showed distinct chromatolysis, many of the cells being "ghost-like."

And, finally, a word in explanation of the conflicting results of the removal of the thyroid and parathyroids. There seems to be a strong similarity between the "tetanic" symptoms which follow parathyroidectomy, the acute "neurotic" symptoms which follow thyroidectomy, and the toxic phenomena of thyroidism. It would seem to me that the essential result of thyroidectomy is an artificial myxœdema (Horsley's "mucinoid" and "marasmic" stages), and that the acute or "neurotic" effects of thyroidectomy are accidental and, like the symptoms of parathyroidectomy, may be accounted for (1) by the youth of the animal operated upon—the "acute" symptoms are always most common in young animals and are usually absent in old animals; (2) the interference with the rich nervous connexions of the thyroid during the operation; and (3) the wounding of the thyroid, in consequence of which colloid is spilt and thyroidism is produced by absorption of the juice. Where surgeons meet with this mishap it is common for them to have a more than usually distinct febrile reaction and tetanic symptoms after the operation. In the removal of the internal parathyroids, which are usually incorporated in the deep surface of the thyroid, the thyroid cannot escape severe manipulation or even actual wounding.

Edinburgh.

CARIES OF THE SPINE: MODERN METHODS OF TREATMENT.

BY NOBLE SMITH, F.R.C.S. EDIN., L.R.C.P. LOND.,
SURGEON TO THE CITY ORTHOPÆDIC HOSPITAL; SURGEON TO ALL SAINTS' CHILDREN'S HOSPITAL.

DURING recent years this disease seems to have been selected by surgeons for experimental and violent methods of treatment. The excitement produced among the public by the circulation in the lay press throughout the world of M. Calot's revival of "forced reduction of the deformity" has scarcely subsided when it is proposed that every case of caries should be operated upon with the view of removing the tuberculous bone. This suggested operation is based apparently upon the following assertions—firstly, that sufficiently good results cannot be obtained by other methods, and secondly, that it is desirable to remove every portion of diseased bone in tuberculous osteitis. I will endeavour to controvert both these contentions. First, if the spine be fixed thoroughly by means of an efficient apparatus such as I have frequently described, and gradually or rapidly extended in accordance with the comfort of the patient, the adjustments being made with careful accuracy by the surgeon himself and the health of the patient maintained by proper food and medicine, almost every case of caries of the spine will be cured. Operations are undoubtedly called for in a considerable number of cases and occasionally it may be desirable or necessary to cut down upon diseased parts and remove pieces of necrosed bone or give vent to the contents of a chronic abscess. Should an abscess appear it is desirable to open it up as soon as possible and to scrape it out and, in fact, to adopt the methods of modern surgery in the treatment of chronic abscesses as far as possible. If this plan of treatment be carried out it may be confidently expected that every patient whose health has not been already undermined by the disease, or, in other words, every patient who has not become the subject of general tuberculosis, will be cured. In no case where I have been able to carry out this treatment thoroughly has there been any increase in the deformity after the treatment has been commenced and in the large majority the deformity has been reduced. The experience of such results gives me reason for dissenting from the assertion that other methods than that of extended operation have not been successful. Secondly, with regard to the removal of the tuberculous bone it has not yet been proved that we can define with certainty the exact area to which the disease is limited, and even if we could define this area the operation would not prevent further occurrence of disease in other parts after we had removed that which existed. It is only necessary to examine pathological specimens of spines affected with this disease to realise the almost insuperable difficulty of removing even that portion of the bone which is obviously diseased, and as to taking away every part which may be involved the accomplishment is practically impossible.

The annexed illustration shows a specimen in St. Bartholomew's Hospital, No. 1064. It consists of a vertical

Section of spinal column from fifth dorsal to second lumbar vertebra inclusive. Destruction of part of the bodies of the tenth and eleventh dorsal vertebræ has taken place and the bodies of the other vertebræ are seen studded with tuberculous cavities.

section of a portion of the spine, including the fifth dorsal to the second lumbar vertebra. Between the tenth and eleventh dorsal vertebræ there is destruction of bone

Digitized by Google

leading to angular deformity, but in other parts of all the vertebræ shown, hollow spaces, more or less cup-shaped, exist. This is doubtless an exceptional specimen, but even when there is far less implication of the bones the removal of the diseased parts may still be unattainable.

In dealing with tuberculous disease we have to conduct a contest between the nutrition of the patient and the disease, and it is of the first importance to render the soil unfit for the tubercle bacilli. Improvement in the patient's vitality will overcome the bacilli and perfect fixation will permit local repair to take place. This is surely a well-established doctrine and it has been proved to be true in practice. There can, of course, be no doubt, speaking generally, that in cases of degenerated and broken-down tuberculous bone the sooner and more completely it is removed the better. In caries of the spine this can be effected by the early opening of abscesses and their treatment as above referred to, and sometimes by more extensive operations for removal of bone, but to cut down upon every diseased spine and attempt to remove all affected osseous tissue is a plan of treatment which can hardly commend itself to cautious surgeons. Further, to remove the laminæ and pedicles for the purpose of approaching the diseased parts is to remove those portions of the vertebræ which are, as a rule, alone free from disease and upon which we should rely for maintaining the stability of the spinal column during the process of repair.

Queen Anne-street, W.

THE TREATMENT OF CHRONIC ULCER OF THE LEG.

BY CHARLES HERBERT THOMPSON, M.A., M.D. DUB., M.R.C.P. LOND.,

LATE CLINICAL ASSISTANT TO THE HOSPITAL FOR DISEASES OF THE SKIN.

THE treatment of chronic ulcers of the leg, especially in out-patient practice, is often so unsatisfactory that it seems worth recording the results I have obtained in a large number of these cases by adopting an old but comparatively seldom used method of treatment which I have found very successful in dealing with this painful condition. The method is that of careful and systematic strapping of the leg, the ulcer being completely covered in and no other local remedy being employed.

Some years ago, when house surgeon to the Metropolitan Hospital, I was requested by one of the visiting surgeons to strap a chronic ulcer on a patient's leg situated over the tibia. The man had been attending the out-patient department for six months and had been given the usual routine remedies with little or no benefit, but his ulcer soon improved when strapping was commenced and was well in a few weeks. The rapid healing of this ulcer induced me to give treatment by strapping a more extensive trial and I have now treated in this way between thirty and forty ulcers of the leg with very satisfactory results. I can only recall four patients, all elderly women, in whom this method of treatment failed. In these instances it had to be discontinued as it caused irritation of the leg, but it is probable that had these patients rested sufficiently and had the strapping been changed more frequently the treatment would have been as successful in their cases as it has been in all others in which I have regularly carried it out. The strapping used was the ordinary adhesive plaster spread on stout, pliable holland and supplied in 12-yard rolls, 16 in. wide. It must be cut into various lengths according to the size of the leg, each length being about 1½ in. wide and applied so that the strips overlap by ½ in. It is best to include the foot, commencing at the base of the toes and carrying the strapping up the leg to 3 in. or 4 in. above the ulcer, which is thus completely covered in. A strong calico bandage should then be applied over all, reaching from the toes to the knee, and this should be changed by the patient daily or as often as it becomes soiled.

Occasionally small vesicles and excoriations form beneath the strapping or the skin round the ulcer may become irritated by retained discharge. This is less likely to occur if the patient can rest, and is not of much importance, as the excoriations readily heal on the application of an ointment composed of equal parts of zinc ointment and soft paraffin, applied on small pieces of lint, the whole being then covered in with strapping. Care should be taken that the lint is not placed too close to the ulcer, as otherwise it may interfere with the firm pressure which should be maintained by the strapping on the healing edges. It is usually sufficient to change the dressing twice a week, but if the ulcer is large and there is much discharge it may be necessary at first to renew it more frequently and if there is much inflammation of the skin around the ulcer it is well to subdue this before commencing to strap in the first instance.

At the Hospital for Diseases of the Skin, Blackfriars, where many out-patients attend with ulcer of the leg, the surgeon to whom I was acting as assistant kindly allowed me to treat many of his cases with strapping. On referring to my notes of ten of these patients I find that their ages varied between thirty-three and sixty-three years, five of them being over fifty years. Several of the ulcers had an area of about the size of a crown piece, others were smaller. Nearly all had had months of hospital treatment up to the time strapping was commenced, but with little or no improvement, and in some instances the ulcers had latterly been extending. Many of the patients had varicose veins and œdematous legs and they almost invariably expressed themselves as much relieved soon after treatment was begun. The average number of strappings required in each case before healing was completed was twelve. After the ulcer has healed the patient should be directed to wear an elastic stocking or a Martin's rubber bandage. The latter is to be preferred for hospital patients and should be worn over a soft calico bandage which helps to prevent the irritation which sometimes arises when the rubber is immediately in contact with the skin.

The improvement which this treatment leads to is, of course, largely due to the support which the strapping gives to the limb. The pressure causes diminution of the œdema and a more satisfactory condition of the circulation of the leg, and, in consequence, the granulations become vascular and active, the ulcer becomes healthier, and new skin gradually spreads over it from the margin. This method of treatment is no doubt somewhat troublesome and requires more time than can usually be given to individual out-patients, but there is nothing to prevent its being carried out in private practice or by students under careful supervision in hospitals to which schools are attached. There is no special novelty claimed for the method, which has long been a recognised one, but an experience extending over many years in various out-patient departments in London has shown me how comparatively seldom it is tried and I venture to assert that for chronic non-specific ulcers of the leg of moderate size, where the patient is unable to rest, none of the usual methods of treatment yield anything like such satisfactory results as that which I have endeavoured to describe.

London.

A CASE OF OBSTRUCTED PREMATURE LABOUR.

BY W. J. LUBECK, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A., D.P.H. CANTAB.,

RESIDENT MEDICAL OFFICER TO THE TOWER HAMLETS DISPENSARY.

THE following case may probably be of some interest to the readers of THE LANCET.

On August 5th, at 7.30 A.M., I was called to see a woman, a multipara, aged thirty-eight years, who was about seven months pregnant. A certificated midwife who was present told me that the patient had had a fall three days previously and that the "pains" had set in at about 3 P.M. on the previous day and had gradually increased in severity. She added that they were typical labour pains but that they made no impression on the os, which was then of the same size as it had been on the previous night. I found the patient quite exhausted. The head was presenting, the membranes were intact, and the os was abnormally thickened and tough, barely admitting a finger. I ordered 15 gr. of chloral and left. I saw the patient again at about 12 noon—i.e., twenty-one hours after the pains had set in—and I found that the os was almost the same size as it was when I saw her previously. I learned that the patient had slept for a couple of hours and had awakened refreshed only to be soon prostrated with the

Digitized by Google

pains, which came on with redoubled vigour. I then resorted to artificial dilatation with Champetier de Ribes's bag, and with some difficulty got it into position and retained it for about two hours, at the end of which time I was surprised to find that the os even then only admitted two fingers, and this with difficulty, there being thus hardly any appreciable increase in size. I ruptured the membranes, and, nothing else being at hand, made a couple of slight snips in the cervical tissues with a pair of scissors. I then performed bipolar podalic version and succeeded in bringing down a foot. The tough cervical band grasped the thigh so tightly that the leg in a few minutes became almost black from the obstructed circulation. After about half an hour the cervix showed signs of relaxing and the rest of the body up to the neck followed with difficulty. A further complication now occurred by the after-coming head being extended and much too large to get through the imperfectly dilated os. As it could not be extricated by the ordinary methods, forceps were tried but without avail. I was then preparing for craniotomy, when a strong pain, aided by stronger traction, succeeded at last in expelling the head. A further complication in this interesting case was a prolapse of the anterior vaginal wall containing the partially distended bladder (cystocele). The placenta was expelled soon after but was incomplete, there being numerous small islets of placental tissue wanting. I found it necessary to insert my hand four times to remove portions of the placenta with my fingers and also to introduce a curette—which was done by a colleague—to scrape away the remnants which had escaped the fingers. A hot iodine douche was then given and was ordered to be repeated once a day and a hypodermic injection of ergotin and strychnine administered. Hot-water bottles were placed to the feet and other precautions were taken to counteract the collapse of the patient. She soon rallied and at the time of writing, a week after the delivery, is quite well, not having had any hæmorrhage or offensive discharges whatever.

The interest of the case, to my mind, lies in the following facts: (1) an abnormally tough and thickened cervix; (2) the unsuccessful artificial dilatation; (3) the evidently diseased placenta; (4) the presence of cystocele; and (5) the value of strict antiseptic precautions, for notwithstanding the number of times that the above complications necessarily entailed manual insertion not the slightest indication of sepsis appeared. I used the pellets of perchloride of mercury specially designed for private use.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON AUSCULTATORY FRICTION AS AN ADJUNCT TO AUSCULTATORY PERCUSSION IN ABDOMINAL EXPLORATION.

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND., AND A. C. PEARSON, B.A. CANTAB.

THE method which is briefly described in this note is not new, although it was recently re-discovered in the wards of St. George's Hospital.[1] Professor Bianchi had introduced it in 1894 in connexion with the Biazzi-Bianchi phonendoscope, but it does not appear to have come before the practical notice of the profession in this country. The expectations which had been raised as to its clinical value have not been fully realised; on the other hand, it is capable of so much precision within a limited range of use that it is worthy to be brought more prominently than has hitherto been the case before the notice of clinical workers. The principle and the procedure are analogous to those of auscultatory percussion. Any amplifying stethoscope, such as the phonendoscope, will have an advantage over the common stethoscope, but the latter is quite sufficient for all ordinary purposes. If the finger be drawn lightly over the skin away from the spot where the chest-piece is applied the otherwise inaudible sound will be loudly heard through the stethoscope, but only for a short distance, beyond which it will cease. The edge of the nail or the top end of a pencil or the like will answer the same purpose as the finger. If the chest-piece be applied over a hollow organ, such as the stomach, the intestine, or even the lung, the friction will continue to be perceived for a considerable distance without any diminution until it abruptly ceases to be heard. By repeating the operation in radiating fashion an outline can be drawn of the vanishing points all around, and on testing this it will be found to correspond exactly with the superficial outline of the organ. It was in mapping out a distended colon that the method was re-discovered at St. George's Hospital. No more striking illustration could be obtained of the fine localising power of the method, for in this case the boundary had to be drawn between the distended gut and the distended stomach. No other method can do this with the same definiteness, and the method also stands alone in the ease of its performance and the absence of any disturbance to the patient, whose state may forbid rougher means of examination. The method is applicable to the study of other regions and organs, but upon this we need not enter at present, as further reference will be made to it elsewhere.[2] The practical experience hitherto gained shows that the method is nowhere so successful as in mapping out the distended viscera in the abdomen, provided the abdominal walls themselves be not unduly tense. Excessive tension of the parietes puts a stop to its differentiating power. With this reservation the results are such as to deserve the attention of clinicians.

[1] Dr. Ewart states that to Mr. Pearson belongs the credit of having found out for himself this additional means of determining the boundaries of viscera and of having called attention in the case in which he had first applied it to the fine results which may be obtained by auscultatory friction.—ED. L.

SARCOMA OF THE SOFT PALATE, &c.

BY JAMES WILSON, M.D.R.U.I., F.R.C.S.ENG.,
SURGEON TO THE HAVERFORDWEST INFIRMARY.

THE following report may be of interest, as it is the subsequent history of a case, reported in THE LANCET,[3] of sub-parotid and retropharyngeal sarcoma successfully operated on.

It was noticed in January, 1897, that the growth had recurred and occupied the soft palate, invading the right pillars of the fauces, rendering swallowing painful and difficult, and causing considerable dyspnœa. It also involved the right side of the hard palate, especially the alveolar edge. The main central growth was of the size of a small hen's egg, but the edges were ill defined, though several little outlying lobules could be felt. After consultation with Mr. Jacobson it was decided to operate, and on Feb. 12th I, with the assistance of Dr. Stamper, Mr. Williams, and Mr. Mills, removed the growth. Chloroform was given and a preliminary laryngotomy was performed, the pharynx being plugged. Shortly after the patient became livid and apparent respiration ceased, the pulse remaining fair. On lowering the head and rubbing the epigastrium and performing artificial respiration for about five minutes colour returned and natural breathing began again. An incision was then made along the right side of the nose, round the ala, and through the middle of the lip; this flap was rapidly dissected from the bone and bleeding was stopped by pressure and torsion. The hard palate was sawn through in the middle line after removing the right incisors, and the upper jaw was cut through transversely just below the level of the nasal bones. The separated bone was then drawn forward and an attempt was made to separate the growth. To deal with it properly, however, the right cheek had to be slit back to the masseter and much trouble was experienced in getting it all away. The soft palate was removed on both sides and the buccal mucous membrane was dissected off from the masseter, leaving its fibres bare and glistening; all the soft parts were removed as thoroughly as possible. Hæmorrhage was stopped by Pacquelin's cautery and iodoform was dusted over the surface; the skin incisions were brought together by silver wire. The

[3] THE LANCET, June 27th, 1891, p. 1429.

Digitized by Google

laryngotomy tube was removed before the patient regained consciousness. The temperature, which never rose above 101°F., became normal in three weeks. Four weeks after the operation the patient had a severe fall downstairs, resulting in partial paraplegia, which lasted seven weeks. This all ultimately cleared up. At present there is no evidence of recurrence, the only complaint being some stiffness of the jaw. Sections were taken of the main tumour and a neighbouring gland removed during the operation. Both resembled the original growth—"mixed glandular sarcoma resembling in structure the parotid gland"—with the addition of larger patches of chondrification than one usually gets in such growths.

Haverfordwest.

PYÆMIA DUE TO ALVEOLAR ABSCESS.

By JOHN EDMONDSON, M.B., C.M. EDIN.

IN THE LANCET of June 25th, 1898, Dr. F. Willcocks reports a fatal case of pyæmia following alveolar abscess which occurred in the Evelina Hospital for Sick Children. The following is another example of the serious effects which may result from this cause. A few years ago I attended a boy, aged fifteen years, who on account of a gum-boil had an incisor tooth extracted by a chemist. Two days later he began to complain of increased pain in the gum and also in the face. There was a quantity of pus in connexion with the socket of the canine tooth and with the three adjoining teeth, all decayed, of the same side. The cheek of the same side presented the typical appearance of a case of diffuse suppurative cellulitis. The general symptoms were those of slight jaundice, cough, pain in the chest, hæmorrhagic sputum (due to consolidation of the base of the right lung), delirium, and great depression and emaciation. There was no appreciable hepatic or splenic enlargement. The temperature was 105° F. and the pulse was 140. I extracted the three decayed teeth and made several incisions down to the cellular tissue of the face, and this was followed by gradual improvement which went on for about two weeks. An abscess then formed in the lower end of the humerus, which was opened and drained. A little later another abscess formed in the lower end of the radius, which was similarly treated. The patient continued to be ill more or less for several months but ultimately recovered, though he still suffers from stiffness of the elbow-joint and wrist-joint in consequence of the suppuration.

Dr. Willcocks says that pyæmia from alveolar abscess is rare, and he points out the uselessness of any treatment except the immediate extraction of the carious teeth in the case of abscess due to temporary teeth. This, I think, would apply equally well to the same condition when it is due to abscess caused by permanent teeth. In this case had all the carious teeth been removed early no doubt the patient would have been well in twenty-four hours. I am indebted to Dr. Kershaw of Farnworth, near Bolton, in whose practice this case occurred, for permission to report it.

Burscough.

SUPERSTITION IN SOMERSET.—The Wells city magistrates last week investigated a charge brought against a man named Elliott for unlawfully using "certain subtle craft, means and devices" to deceive a person on July 20th. It appeared that the defendant had informed a woman that somebody had been "at her child again and cast a devil into her," and ultimately he consented to drive the devil or witch out of the child for 7*s.* 6*d.* The child, however, became worse and eventually died. Defendant handed to the magistrates a number of testimonials from people who had asked his advice. The writer of a letter sent from Shepton Mallet said that her daughter was getting on "wonderful," another from a farmer expressed thanks for the cure of two cows and a mare whose illness was due to witchcraft. It was stated that the defendant had received £120 from 200 people who had consulted him in Bristol, Langport, Glastonbury, Shepton Mallet, and nearly all parts of the county. The magistrates sentenced Elliott to two months' imprisonment with hard labour.

EAST LONDON HOSPITAL FOR CHILDREN.

A CASE OF LARYNGEAL STRIDOR: REMOVAL OF ADENOID VEGETATIONS.

(Under the care of Dr. EUSTACE SMITH.)

THERE are probably several distinct causes of laryngeal stridor in children and the following case, especially when considered in connexion with the others recorded by Dr. Eustace Smith, shows that the presence of post-nasal "adenoids" is no unimportant factor in its etiology. The area of the results produced by these troublesome vegetations is steadily growing, and they are now held responsible for many more symptoms than was the case a few years ago. For the notes of the case we are indebted to Dr. J. Shardlow, resident medical officer.

A boy, eight months old, was admitted to the East London Hospital for Children on May 18th, 1898, with a history of (1) having made a "crowing" noise and (2) of having difficulty in swallowing, both dating from birth. He was a full-term child and was said to have had "snuffles" when six weeks old. The parents were healthy; they had no other children. On examination the patient was found to be well nourished; he lay fairly comfortably in bed, the alæ nasi working slightly. He was evidently rickety—there being marked "bossing" of the frontal bones, thickening about the radial epiphyses, and "beading" of the ribs. The anterior fontanelle was large and the edges of the bones forming the boundaries of the fontanelle were greatly thickened. The lips were of a good colour and a distinct stridor was heard when the patient was lying quietly in bed, but when attempts at swallowing or crying were made he became extremely cyanosed and during expiration not a sound was heard, but in inspiration a very loud "crowing" occurred and was audible in any part of the ward. The mouth was kept constantly open and well-marked depressions were seen above the alæ nasi. Numerous adenoid vegetations were felt in the naso-pharynx on examination with the finger. The hair was rather profuse and the eyebrows were well marked. There was no sign of congenital syphilis. In the chest there was well-marked infra-mammary recession on both sides, and there was a depression at the xiphisternum. A few rhonchi were heard in the lungs, otherwise they were normal. The liver was enlarged and the spleen could not be felt. On May 19th, under chloroform, Dr. Shardlow removed the adenoid vegetations with the aid of the curette and the finger-nail. On the 20th no stridor was noticed when the patient was lying undisturbed, but when taking food he got attacks of dyspnœa and "crowed" in inspiration. The temperature was 101·4° F. and there was a considerable quantity of nasal discharge. On the 27th the temperature became normal and for the first time since admission a noise was heard during expiration when the patient attempted to cry. Inspiratory crowing was still present, but only when the patient cried. He had still a free nasal discharge. On the 31st the nasal discharge had entirely stopped under the influence of an application of ten minims of hazeline to an ounce of boric lotion. "Crowing" was still present; occasionally it was heard during the day, but frequently at night. The patient still had attacks of dyspnœa when food was being given. From May 31st to June 9th he had nasal discharge again. "Crowing" occurred until the 10th. Very little difficulty was experienced now in swallowing. On the 20th no "crowing" had been heard since the 10th, there was no difficulty in swallowing, and the patient was discharged from the hospital. The patient was seen again on July 20th and the mother stated that she had never once heard the "crowing noise" since the patient left the hospital. Thus the stridor disappeared just about three weeks

Digitized by Google

after the operation—i.e., after the removal of the adenoid growths.

Remarks by Dr. SHARDLOW.—Dr. Eustace Smith pointed out in two papers which appeared in THE LANCET of May 25th, 1895, and March 19th, 1898, that there is a close relationship between some cases of laryngeal stridor and adenoid growths, so much so that if the vegetations be removed the stridor disappears. In this connexion the above case is very interesting and confirms the opinion expressed in the papers mentioned. I am convinced that recovery in the present case was delayed by the meteorological conditions which prevailed at the time, because when the weather was damp the patient seemed to be much worse and the nasal discharge was more profuse. The effect of the removal of the adenoids in this case, I take it, was very striking. Not only did a laryngeal stridor which had been present since birth disappear in three weeks, but also the child showed much more intelligence and improved in every way. For permission to publish the notes of the case I am indebted to Dr. Eustace Smith.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

A CASE OF ACUTE INTESTINAL OBSTRUCTION; LATENT HERNIA; LAPAROTOMY; REDUCTION OF HERNIA FROM WITHIN; DRAINAGE; RECOVERY.

(Under the care of Dr. ALEXANDER.)

IT can hardly be disputed that for strangulation of inguinal or femoral hernia the ordinary external incision is the best, as the hernia is situated comparatively superficially and so no deep dissection is required, but in the case of an obturator hernia the sac is so deeply placed that the dissection needed to reach it is difficult, and therefore an abdominal section is preferable, especially when we consider the slight local indications of the hernia. In cases of inguinal or femoral hernia, if the local signs of a hernia are wanting, owing to the small amount of bowel involved, a laparotomy offers the best chance of success, as the cause of the obstruction of the bowel will then certainly be discovered, though the dangers of sepsis are undoubtedly increased. For the notes of the case we are indebted to Mr. C. E. Morris, senior house surgeon.

A boy, aged fifteen years, was admitted to the Royal Southern Hospital, Liverpool, on the afternoon of March 2nd, 1898, giving the history that six days previously he had been, when dismounting from a pony, suddenly seized with very severe pain in the right side of the abdomen. He vomited and three loose stools containing a little blood were passed in rapid succession. From the onset of the attack up to the admission of the patient to the hospital no stools or flatus had been passed. All nutriment taken had been vomited. The pain had become less severe but was still greatest in the right side of the abdomen. There had been no tenesmus. On admission the patient's eyes were sunken and the features were drawn and pale. The legs were extended and the abdomen was found to be uniformly enlarged, firm, tympanitic on percussion, and not moving with respiration, but it was not hyperæsthetic. No special tumour could be found. The temperature was 98·4° F. and the pulse was 88 and small. It was decided to explore the abdominal cavity. Accordingly, a few hours later the patient was prepared for operation and anæsthetised. On further careful examination it was thought that a very small indefinite tumour could be felt near the middle of the right Poupart's ligament. The abdominal cavity was opened by an incision above, and nearly parallel to, the right Poupart's ligament and was found to contain much clear fluid; the small intestines were discoloured and distended. A little knuckle of bowel, just sufficient to occlude its own lumen, was found tightly grasped by the right crural ring. This was cautiously and easily withdrawn and as its condition, although very deeply congested, did not suggest gangrene it was not further interfered with. When the hernia was being withdrawn a quantity of dark sanguineous fluid came away from the sac and was prevented by sponges from entering the abdominal cavity. The wound was closed, a glass drain carrying a piece of double cyanide gauze being inserted into the peritoneal cavity. On March 3rd the drain was removed. The pulse ranged from 100 to 120 and the temperature was 98·4°. On the 4th ten soft stools were passed. The patient made a good recovery, with the exception that suppuration occurred along the suture tracks, and on the twelfth day after the operation left orchitis developed, suppurated, was incised and healed rapidly.

Remarks by Mr. MORRIS.—The points for consideration suggested by the case are as follow: 1. The difficulty of diagnosing a small femoral hernia (almost a Littré's hernia), especially when there is great distension of the abdomen. 2. Rarity of femoral hernia in boys. 3. The occurrence of *left* orchitis after a wound of the right side of the abdomen. Was this caused by the end of the tube impinging upon the left vas deferens or by sepsis travelling in an unusual path? 4. The dangers of peritoneal infection from the hernial sac by the intra-abdominal method of operating are well shown in this case. Had the fluid in the sac been septic or the bowel sloughing it would have been very difficult with sponges to prevent the possibility of peritoneal infection. Moreover, the sac would have had to be dealt with externally afterwards.

Reviews and Notices of Books.

Operative Gynæcology. By HOWARD A. KELLY, A.B., M.D. 2 vols., 1100 p.p., with 24 Plates and 550 Illustrations. Royal 8vo. London: Henry Kimpton. 1898. £3 3*s.* net.

THE announcement that Dr. Howard Kelly was writing a work upon operative gynæcology led us to anticipate its appearance with great interest. The book, which is in two volumes, has now been published and is undoubtedly the most important work upon this subject which has yet been written in the English language. Not only the great excellence of the letterpress, but also the artistic merit of the very numerous illustrations with which it is furnished, renders the work one well worthy of the American school of gynæcology and of the high reputation of its author.

The first two chapters consist of a very full description of the methods to be employed in attaining asepsis and antisepsis, both in hospital and in private practice. The difficulties which beset the perfect sterilisation of catgut has led many surgeons to give up this most convenient form of ligature. From 1890 to 1894 in the Johns Hopkins Hospital the catgut was prepared by soaking in ether and boiling in alcohol under pressure. At the beginning of 1894 an outbreak of sepsis occurred, which was almost certainly traced to the use of catgut prepared in this way. Since 1895 a modification of Krönig's cumol method has been employed with success. This method consists of several steps. First the catgut is heated in a sand bath at 80° C. for one hour, it is then placed in cumol at 100° C. and heated up to 165° C. (331° F.), this temperature being maintained for an hour, and finally it is dried at 100° C., for two hours in a sand bath or a hot air oven, and thence transferred to sterilised glass tubes until used. The process is somewhat troublesome, but as it appears to be efficient it should be of service to surgeons who wish to be certain of the asepsis of their catgut. Schatz's method of disinfecting the hands by immersing them in hot saturated solutions of permanganate of potassium and oxalic acid after a thorough preliminary scrubbing with hot water and soap is recommended, and the great importance of the preliminary washing for a definite length of time is insisted upon. The chapter upon the Topographical Anatomy of the Pelvis is remarkable for the great beauty of the illustrations, especially those illustrating the anatomy of the small intestine. The anatomy and action of the levator ani muscle are well described. Under Gynæcological Examinations the great value of photography is pointed out and the chapter is illustrated by a number of drawings obtained in this way of the various forms assumed by the abdomen when distended by tumours or other conditions. The examination of patients in the dorsal and other postures is fully described and the great value of rectal

Digitized by Google

examination after distension of the bowel by air is drawn attention to. From our own experience we can fully endorse all that the author says as to the excellence of this method of examination in difficult cases. Examination of the rectum itself in the knee-chest position through a long straight speculum is recommended, this method being of special value when it is wished to localise the opening in cases where a pelvic abscess has burst into the bowel. Under Diseases of the External Genitalia a very interesting case of fibro-myoma of the round ligament growing within the inguinal canal is recorded. The author directs attention to the fact that negresses appear peculiarly liable to the curious condition known as elephantiasis of the vulva. He considers it to be the result of chronic inflammation and blockage of the lymphatics, the commonest exciting cause being syphilis. A case of adeno-carcinoma apparently beginning in the left vulvo-vaginal gland is figured, but, as is pointed out, Gottschalk and others have shown the presence of adenoid elements in the upper part of the labia majora and it is possible that the tumour rose from these rather than from the gland of Bartholin. In considering complete tear of the recto-vaginal septum the author recommends a denudative operation, the posterior vaginal column being as far as possible preserved, while Emmet's operation is recommended for the common condition, the result usually of much childbearing, known as a relaxed vaginal outlet. Dr. Kelly is inclined to agree with Bumm that cases of true gonorrhœal vaginitis are rare and that most cases of so-called gonorrhœal vaginitis arise from secondary irritation due to the stagnation of purulent discharges from an infected cervix. More than one-third of the first volume is taken up with the chapters upon diseases of the bladder, urethra, and ureters. An important section is that devoted to the topography of the bladder, the author laying down certain definite landmarks the general use of which in describing the appearances noted in cystoscopy would greatly facilitate their localisation. A very good and full account is given of cystoscopy as practised by the author, an atmospheric dilatation of the bladder being obtained by posture and a short, straight cystoscope being used. This method is of the greatest practical value and has placed the treatment of diseases of the bladder upon a more certain and scientific basis. It is easily practised, is not attended with any danger if due care be taken, and deserves to be more widely known and used than it is at the present time in the treatment of bladder and renal affections. It is quite impossible for us in the course of a review to notice all the points of interest alluded to in these chapters. They are well worth reading by all who are interested in the subject, and the cases and results quoted show how extremely useful this method of cystoscopy has proved to be in the diagnosis and treatment of diseases of the urinary tract. Under Vesico-vaginal Fistulæ the great advances which have been made in the treatment of the worst cases of this kind are noted and the various ingenious methods described which are now possible in place of the operation of colpocleisis, until recently the only resource in the treatment of many of these most distressing cases. The author has come to the conclusion as the result of his examinations of the bladder that in almost all the cases of a so-called irritability of the bladder there is some hyperæmia of the trigone. In cases of this kind which do not yield to general treatment he recommends topical applications to the congested region. A full account is given of the present views as to the bacteriology of cystitis, and the important fact is pointed out that the mere presence of bacteria is insufficient to cause cystitis in the absence of any predisposing cause. In the section on the treatment of chronic cystitis there is an account of Dr. Clark's method of employing a ubber balloon coated with various ointments and introduced into the bladder, and a case is quoted in which the use of this balloon covered with a 10 per cent. ichthyol and gelatin ointment gave marked and rapid relief. The unfortunate cases which occur from time to time in which a surgeon cuts down upon the wrong kidney should be greatly diminished in number by the more extended use of catherisation of the ureters, first practised by Simon, reintroduced by Pawlik, and carried to perfection by the author of this work. What a wide field has been opened up and how our knowledge has been increased is shown by the fact that no less than 80 pages are devoted to affections of the ureters. When we read that the author is in the habit of passing a catheter up to the kidney and washing out the pelvis of that organ we naturally look with some care to find what are the dangers of such an operation and what are the risks, if any, entailed upon the patients. Upon this point the results are quite reassuring. In only four of the cases in which the author has catheterised the ureters have the patients suffered from fever, and in all four of these cases the urine contained pus coming from the pelvis of the kidney. When we consider the readiness with which infection spreads from the bladder to the ureter it is obvious that these operations can only be practised safely with the strictest aseptic precautions, and this is a point upon which Dr. Kelly very strongly insists.

The cases recorded in which the diagnosis of stone in the kidney has been confirmed by the use of a wax-tipped bougie are of the greatest interest. A full account is given of the various methods available in the treatment of a damaged ureter, an accident which may happen even to the most skilful and experienced operator. The rest of the volume is taken up with the consideration of operations upon the cervix, inversion and prolapse of the uterus, vaginal hysterectomy, vaginal extirpation of submucous fibroids, and the uterus as a retention cyst.

The first three chapters in the second volume treat of the general principles common to abdominal operation, the care of the wound and the patient until recovery, and the complications arising after abdominal section. We would call special attention to the very full discussion of the difficult question of drainage after abdominal sections. After an extended experience of all forms of drainage Dr. Kelly has been slowly forced to the conclusion that it is rarely of value and often harmful and the extent to which he has abandoned its use is shown by the fact that 73 out of his first 100 abdominal sections were drained, and none of his last 100. He found while using the glass drain-tube that no less than 44 per cent. of the cases showed some form of organism present. The glass tube was therefore abandoned and gauze drains were tried, but these were found to be equally inefficient. In 1893 Schauta's plan was adopted of draining only those cases in which pathogenic organisms were found on making cover-glass preparations during the operation; later still a drain was employed only when colon bacilli or staphylococci were present in abundance or streptococci in moderate numbers. A further study of the drain when used only in these few cases led to the conclusion that it usually became infected after the operation and that this infection might give rise to serious and even fatal results. The author's present practice is this: when there is any serious contamination of the peritoneum, and therefore danger of infection, from 500 to 1000 c.c. of a normal saline solution are left in the peritoneal cavity and the patient is placed in bed with her feet elevated. A drain is used in abcesses which are walled off from the peritoneal cavity and which cannot be enucleated or drained from the vagina. A drain is also used in cases of widespread peritoneal suppuration where the patient is too feeble to be treated by other means, and it is used as a prophylactic measure in cases of suturing of the intestine where there is any doubt as to the accuracy of the

Digitized by Google

suture or the ability of the tissues to hold the stitches. In performing the operation of hysteropexy the author recommends that silk sutures should be used, passing through the posterior surface of the uterus just below the fundus and including the peritoneum and subperitoneal fat. In 4 cases in which the abdomen was opened from one to three years after the operation had been performed the uterus was found lying in a position of anteflexion from 1¼ to 2 inches distant from the anterior abdominal wall, to which it was connected by slender bands or a thin sheet-like adhesion. The chapter upon Conservative Operations shows what conditions can be treated in this way, and the following remark of the author is we think worth quoting: "In the light of our present knowledge of the pathology of ovarian tumours the attempts to justify the removal of small 'cystic ovaries' must be denounced as unscientific and immoral." The author has had very good results in the treatment of pelvic abscesses, cases of pyosalpinx, and ovarian abscesses in suitable cases by vaginal incisions and drainage. Of 62 such cases 32 were cured and 2 died, of the remainder some were greatly benefited, while a small proportion were no better. In many cases Dr. Kelly recommends the removal of the uterus with the diseased tubes and ovaries. We cannot give his reasons for this in detail, but they will be found in the chapter devoted to this subject, as will also the reasons why he continues to prefer abdominal to vaginal hystero-salpingo-oöphorectomy. The chapter on Ovarian Tumours contains a particularly full account of the interesting class of papillary tumours of the ovary. The author's recommendation in complicated cases of ovariotomy not to hesitate to remove the uterus with the tumour is no doubt sound. For the last three years Dr. Kelly has been limiting the indications for vaginal hysterectomy in carcinoma of the uterus and now prefers, where possible, the more radical enucleation through the abdomen. In this way a wide dissection of the broad ligaments can be made, with a free removal of the pelvic connective tissue out to the pelvic walls together with any enlarged glands found in the pelvis or above the brim. The dangers of this operation are greatly diminished by previously placing bougies in the ureters as recommended by the author. A considerable amount of space is devoted to myomectomy and hystero-myomectomy for fibroid tumours, and the treatment of all the possible complications of the latter operation, of which the author has encountered some thirty-seven, is given in detail. In discussing the question of operations during pregnancy Dr. Kelly gives it as his opinion that this condition does not constitute a contraindication to the performance of necessary operations upon the uterus, ovaries, or tubes. Abortion does not occur as a rule unless the uterus is involved in the operations.

In the chapter on Ectopic Gestation an interesting table is given of the results during the last ten years of operations undertaken with a viable fœtus. 27 mothers have recovered out of 40, or 67·5 per cent., including 15 of the last 20 operated upon. We have no space to do more than mention the contents of the remaining chapters. They treat of the Radical Cure of Hernia, Intestinal Complications, the More Remote Results of Abdominal Operations, and the Conduct of Autopsies and the Making of Protocols. Of the plates and illustrations it is impossible to speak too highly. Many of them are triumphs of the illustrator's art, and the author is to be congratulated not only on his artists, but also upon his publishers who have reproduced the artists' drawings in such a remarkable manner.

We trust that we have given our readers some idea of our appreciation of these volumes. They are of the highest merit, will long remain the standard work upon the subject of which they treat, and should be in the hands of all gynæcologists and surgeons performing pelvic operations.

The Genesis and Dissolution of the Faculty of Speech: A Clinical and Psychological Study of Aphasia. By JOSEPH COLLINS, M.D. New York: The Macmillan Company. London: Macmillan and Co. 1898.

IT is nearly forty years since Broca made his famous discovery, which was at once the starting point of research into cerebral localisation and the origin of the study of the faculty of language. The intervening period has been filled with the records of clinical and pathological observations, the profound analyses and reasonings of some of the most gifted physicians and psychologists, for the problems to be solved have grown in intricacy as time has passed with its ever fresh accession of facts. There is, moreover, a fascination about this study of the distinctive faculty of the human race due to its special position in the sphere of mental physiology which accounts for the ardour with which it has been pursued and the treatises that have been written upon it. The latest of these contributions to its study is the work before us, for which its author received the Alvarenga Prize of the College of Physicians of Philadelphia in 1897. Its appearance is timely, in view of the contributions to the subject made last year by Dr. Bastian in his Lumleian Lectures and the recent clinical studies of Dr. Byrom Bramwell. The work itself is evidently the product of one who has carefully studied the subject and who has arrived at definite ideas concerning it—ideas which do not always coincide with those propounded by others. It is somewhat marred by the use of a phraseology which renders the perusal of the book rather irksome to the plain reader and may perchance interfere with the recognition of its undoubtedly high merits. Perhaps this is unavoidable in the treatment of a subject which is as much psychological as physiological, but it is just this which is making the study of neurology more and more the portion of a few specially trained minds. Nevertheless this book contains so much that is of general clinical interest and its author takes so much pains to clearly define his position that it is safe to predict that it will be read with interest even by those who are unable to follow every point in the intricate discussion of the higher cerebral mechanism. In an introductory chapter Dr. Collins gives his classification of the forms of aphasia—which has the merit of simplicity—and after a short historical review of the subject he enters in the third chapter into a discussion of the Genesis and Function of Speech, whilst in the next chapter he deals at length with the Conception of Aphasia, where he propounds his views with satisfactory fulness and apt illustration. Using the phrase "zone of language" to comprise that area of the cerebral cortex concerned in the mechanism of the intercommunication of ideas, he points out that this has no strictly defined limits, but that it varies probably with individuals and with races according to the degree of speech acquisition and the richness of language. The zone comprises the reception centres—where sensory impressions, mainly auditory and visual, are received—and the "emissive" centres in the frontal lobe and Rolandic region. In spoken speech the primary revival of the word to be uttered is probably in the auditory centre; whilst in written language this revival probably takes place in the visual centre. The language of signs, or pantomime, is regarded as a form of "internal speech," but we could have wished for a fuller discussion of this, perhaps the most primitive of all modes of language, than is given here. Dr. Collins adheres to the original view of Broca, which locates the speech-centre at the foot of the third left frontal convolution, to which he applies the physiological synonym of the "centre for articulatory kinæsthetic images." He refers to cases of limited subcortical lesion, especially one recorded by Elder, which go far to prove the accuracy of this view. He enters into an interesting discussion to show that there is no ground for assuming a distinctive "graphic motor centre," and

Digitized by Google

shows that there does not exist on record any unequivocal case of pure agraphia, for such as have been reported can be explained by lesions in one or other regions of the zone of language or the subcortical pathways connected with them. Summing this question up, he says: "After taking all the evidence into consideration of whatever nature, that can be cited in favour of the existence of a specialised graphic motor centre, and carefully weighing it, the conclusion is forced upon us that, so far, the advocates of the existence of such a centre have furnished us with no absolute proof. It seems to me entirely contrary to all that we know of speech, from a study of its genesis and its dissociation to look for the existence of such a centre." The next chapters deal individually with motor aphasia and with sensory aphasia, the latter being defined as being due to "the loss of the understanding of words due to interference with the function of association necessary for complete perception." The contrast is clearly drawn and is excellently illustrated by records of well-selected cases. Chapters on Diagnosis, Etiology, Morbid Anatomy and Treatment complete a work which we venture to think will rank high as an authoritative exposition of an abstruse but very interesting subject the bearings of which are largely clinical and the interpretation of which is so intimately concerned with the higher cerebral activities.

Applied Bacteriology. By T. H. PEARMAIN and C. G. MOOR, Members of the Society of Public Analysts, &c. Second edition. London: Baillière, Tindall, and Cox. Pp. xvi.–464. 1898. Price 12*s.* 6*d.*

INASMUCH as a second edition of this work is forthcoming after the lapse of only two years, it may be presumed that it has been found useful by the students, sanitarians, and others for whom it has been written. It has, indeed, a good deal to recommend it, particularly in its chemical aspects, and chemistry is becoming more and more important in modern bacteriology. The chapter on Disinfection, for example, is an excellent one and contains a great deal of practical advice which should be valuable to the medical officer of health. Throughout the book it is evident that the authors' knowledge of chemistry is thorough and well applied. To take a trivial instance, Gram's method of staining is not merely described but explained. Bacteriology, however, has also its biological and pathological aspects, and we should strongly advise the authors, when in the fulness of time a third edition is called for, to secure the services of a competent pathologist to collaborate with them. They would thus avoid such very extraordinary statements as that matter derived from the middle of giant cells (in tuberculosis) will produce tuberculosis in the guinea-pig, although the bacillus is chiefly found at their periphery. We are not aware of the name of the conjuror who has performed this miracle of *technique*. Hitherto we had regarded Metchnikoff, who isolated a single leucocyte containing an anthrax spore and watched it grow in a hanging drop, as the greatest exponent in this line. On page 103, again, we note a table from which we gather that the poisons of leprosy, malaria, and scarlet fever are acquired by intestinal infection. This may be so, but we should like to know on what observations the statements rest. The authors do not appear to have much practical acquaintance with section cutting. The unwary student who follows their directions for the preparation of sections by ether freezing will, we fear, be disappointed in his results; tissues hardened in alcohol should be soaked in water before freezing. Embedding in paraffin is not "seldom employed" and it is quite easy to prepare admirable specimens of actinomycosis without embedding in celloidin. There are some errors in the book due to sheer carelessness, such as the statement that the "diplobacillus" of rinderpest is "from ·3 to ·6 mm. in length and about a third of this in breadth" Other mistakes are philological —e.g., "bacilla" on p. 7, and "one terminal flagella" on p. 206. Some misstatements might have been corrected by a competent physiologist—e.g., the average percentage of urea in urine is said on p. 336 to be 3 per cent. The book, in fact, requires very thorough revision to render it a safe guide. In many respects it is worthy of such revision, for there is a great deal in it which is excellent. The authors have evidently been at pains to bring this edition up to date and they have compressed into comparatively small compass a large amount of important bacteriological fact.

LIBRARY TABLE.

Fonctionnement de la Maison d'Accouchements Baudelocque. Année 1897. Paris: G. Steinheil.—The report of the Maison d'Accouchements Baudelocque is on the same lines as in previous years. There are, however, some points of interest to be noted; one of the most important is the installation of an x ray laboratory. It has been found possible by this means to obtain results of great value in cases of contracted pelvis, and these formed the subject of a discussion at the recent International Medical Congress held at Moscow. The injection of antistreptococcic serum as a prophylactic measure has been continued as in the preceding year in all cases where there was reason to suppose that the patient had been infected prior to her admission to the clinic as well as in cases of infection occurring subsequently. The results obtained have been published by Dr. Wallich in the *Annales de Gynécologie*, November, 1897. During the year the treatment of incomplete abortion has undergone some modification. Prolonged waiting for the spontaneous expulsion of the placenta has been to some extent given up, and now at the end of two to three days after the birth of the fœtus if the placenta is still retained it is removed by the fingers, the cervix when necessary being dilated either by bougies or by small Champetier de Ribes's bags. The rest of the report consists of the usual full tables of results and is a model of what such a report should be.

JOURNALS.

The Journal of Tropical Medicine. No. I., Vol. 1. August 15th, 1898. Price 17*s.* annually post free.—This is an excellent first number of a journal the object of which, as explained by Sir Joseph Fayrer in some introductory remarks, "is the consideration and discussion of tropical diseases and of questions of etiology, hygiene and preventive medicine, or any cognate scientific subjects affecting so large a part of our empire." The original articles in the present number are by Surgeon-Colonel K. MacLeod on Tropical Heart, by Dr. Patrick Manson on the Mosquito-malaria Theory, by Surgeon-Captain Buchanan on Epidemic Cerebro-spinal Fever in India, and by Dr. C. W. Daniels on Filariæ and Filarial Disease in British Guiana. Mr. James Cantlie and Dr. W. J. Simpson are the editors of the journal, which is published by Messrs. John Bale, Sons, and Danielsson, Ltd., Great Tichfield-street, W.

VACCINATION AT BOURNEMOUTH.—At the meeting of the Christchurch Board of Guardians, held on August 15th, it was reported that out of 444 children born in Bournemouth between July 1st and the end of December last year only 163 were successfully vaccinated, and that in the rural district only 129 have been vaccinated out of 222 born.

ROYAL CORNWALL INFIRMARY, TRURO. — The report which has recently been issued shows that during 1897 there were 369 in-patients admitted against 357 in 1896, and that 501 out-patients were treated against 557 in the preceding year. The committee referred in sympathetic terms to the death of Dr. Helm, their late ophthalmic surgeon,

Analytical Records
FROM
THE LANCET LABORATORY.

HALOGENALBUMIN PREPARATIONS.

(LUDWIG WILHELM GANS, PHARMACEUTISCHES INSTITUT, FRANKFORT-ON-MAIN.)

SINCE first meeting with these interesting compounds at the recent exhibition at the British Medical Association in Edinburgh we have had an opportunity of examining them in the laboratory. They are known as halogen-albacids since they contain that part of the albumin molecule which lends itself to halogen substitution in the form of the soluble sodium salt. The halogens are described as being combined in intimate intramolecular combination. The halogen is not given up on treatment with dilute acids or alkalies, but on the approach of an oxidising agent the chlorine, bromine, or iodine is set free. Thus, when weak nitric acid is added to "iodalbacid" a spongy mass separates and the liquid turns a light brown. On shaking this liquid with chloroform it rapidly assumes a violet colour. Similar decomposition is produced when the other halogen compounds are treated in the same way. As is well known, iodine is very readily liberated from iodide of potassium, and this fact often leads to what is known as iodine poisoning after the salt is administered. But "iodalbacid" being an albumin derivative is less rapidly absorbed and is more slowly decomposed than iodide of potassium. In this interesting combination, therefore, iodine, bromine, or chlorine may be very favourably administered. It is probable that iodine acts on the thyroid glands after treatment with iodide of potassium by forming an albuminous substance of the nature of an iodoalbumin. The preparations are of great therapeutic interest and the application of the iodine preparation in syphilis promises to be one of the best means of administering iodine in this disease. An interesting clinical record in this connexion has been published by Dr. G. Zuelzer of the Dermatological Hospital of the University of Breslau.

"EUCRYL" PREPARATIONS.

(MAJOR AND CO., SCULCOATES, HULL.)

The name of these preparations suggests a combination of eucalyptus with the coal tar acids of the cresylic type. On examination of "eucryl" itself this proves to be so. It is a brown, somewhat syrupy liquid exhibiting a strongly alkaline reaction. It is miscible with water in all proportions. On the addition of acid the antiseptic oils are liberated. It is a pleasant and very powerful antiseptic compound. The same combination is contained in an absorbent powder which is guaranteed to contain "eucryl" in amount varying from 5 to 15 per cent. It is important that disinfectant powders should contain a standard quantity of the liquid disinfectant and we found this to be so in the present instance. The absorbent used is a powder resembling brickdust insoluble in water and in acids. "Bath eucryl" is a very pleasing combination of antiseptics and aromatics. It is a light-coloured fluid with an alkaline reaction, the active oils dissolved in it separating on the addition of an acid. On dilution with water, with which it is quite miscible, a very agreeable pine-like smell is evolved. Used in the amount specified it is admirably adapted for the bath, softening the water and exerting a healthful action on the skin. "Phenoforme" again suggests a combination of phenol with formalin and the analytical evidence obtained was quite in accordance with this surmise. It is a colourless fluid evolving on heating a pungent acrid odour characteristic of formaldehyde vapour. It is slightly acid in reaction. The combination must necessarily be a very powerful antiseptic and doubtless affords when diluted a convenient application for cleansing and sterilising surgical instruments.

CHLOROBROM.

(BURGOYNE, BURBIDGES AND CO., 12 AND 16, COLEMAN-STREET, E.C.)

The value of chlorobrom in sea-sickness, sleeplessness and hysteria has been asserted in many cases. Clinical contributions on the subject appeared in THE LANCET of Dec. 9th, 1893, and again in THE LANCET of April 24th, 1897. It is not a secret remedy, for the composition of its active ingredients is published and communicated to those who wish to prescribe the combination. The chief constituent is chloralamid of which it contains 30 grains in each fluid ounce. Chloralamid is a compound of chloral anhydride and formamide, and when used as a hypnotic is said to have no undesirable influence on the pulse, respiration, or temperature. The above firm, we believe, were the first to introduce the preparation "chlorobrom," which is a brown fluid with a strong taste of liquorice.

VIN URANÈ PESQUI.

(AGENCY: FASSETT AND JOHNSON, 31 AND 32, SNOW-HILL, E.C.)

This wine is prepared in Bordeaux and contains nitrate of uranium, bromide of lithium, pepsin and quinine. The essential constituent is uranium nitrate, which has been given with good effect in diabetes according to an article in THE LANCET.[1] According to a pamphlet before us cases are recorded where the reduction of sugar in the urine was from 80 grammes per litre to 1·70 grammes. The vehicle is said to be old Bordeaux wine (Medoc). It contains some sugar. We cannot regard the mixture as at all palatable, and the ingredients, if they are valuable at all in the treatment of diabetes, might with advantage be exhibited in another way. We do not think wine is a proper or suitable channel for administering the drugs indicated, which are said to be useful in obviating waste in diabetes. We obtained satisfactory evidence of the constituents enumerated and in addition the wine showed the following composition: alcohol, by weight 8·79 per cent., by volume 10·91 per cent., equal to proof spirit 19·11 per cent.; extractives, 8·24 per cent.; and mineral matter, 0·27 per cent.

PATENT NON-POISONOUS MATCHES.

(THE MERTON MATCH CO., MERTON ABBEY, S.W.)

We are quite prepared to admit that these matches do not contain any harmful ingredients. We could find neither phosphorus nor sulphur in the tips and hence on ignition no phosphorous or sulphurous fumes were evolved. This in itself is an improvement, but from the point of view of a satisfactory lighting match we cannot say much in their favour. To start with, the match frequently requires repeated rubbing before it ignites and when ignition does occur it is of the nature of a spiteful flare. The rubber on the box contains amorphous phosphorus. We have examined the tips and the only ingredients we found which are common to other matches were powdered glass, glue, and chlorate of potash. To say that they give pleasant fumes is a slight exaggeration. We should gladly welcome a match which is satisfactory alike to the user and to the persons engaged in its preparation, but we are not prepared to say that the matches under examination possess all the attributes claimed for them. These remarks apply also to the wax vestas, fusees, and "flamers" which have also been submitted to us.

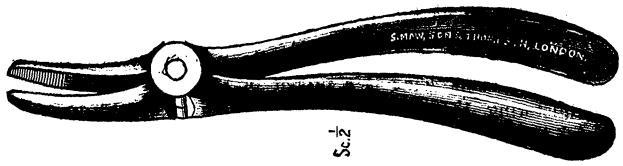
New Inventions.

WIRE SUTURE-CASE.

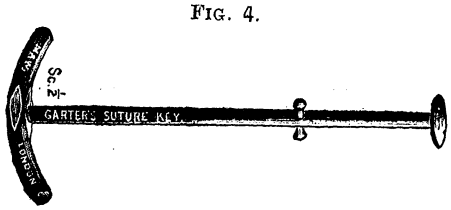
To facilitate wire suturing I have devised a case containing in small compass all my instruments for suturing fractures, whether of maxillæ, patellæ, or long bones. It has been made to pattern by Messrs. S. Maw, Son and Thompson and has been so arranged that the inside tray may be lifted out and its contents boiled in the steriliser without disturbance. The case contains bayonet-shaped drills, silver sutures of varying

FIG. 1.



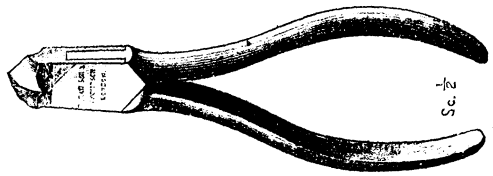
thickness, pliable needle, forceps, &c. The needle (Fig. 1) is made of plated copper-wire, with an eyelet at one end. This having been passed through the second drill-hole may be threaded for the purpose of returning the wire. Being of soft metal the needle is readily bent to any required angle. The spoon (Fig. 2) protects the tissues by receiving the point of the drill and also of the wire and

FIG. 2.



gives the latter a turn in the desired direction. The wire may then be seized and lifted from the floor of the mouth or depth of wound by the long-bladed forceps (Fig. 3).

FIG. 3.



When the suture is ready for twisting the key (Fig. 4) may

FIG. 4.

be used in the manner described in THE LANCET of Feb. 26th, 1898, p. 571 (also Dec. 3rd, 1892, p. 1266). The side cutters (Fig. 5) sever the suture at any required point.

FIG. 5.

Hitherto there have been two great difficulties in the wiring of bones—(1) the drilling and (2) the return of the wire through the second channel made. The first I have overcome by using a dental engine and the second by devising the instruments described above.

T. S. CARTER, L.D.S.R.C.S. Eng.,
Honorary Dental Surgeon to the General Infirmary, Leeds.

EXHIBITION O ROENTGEN RAY WORK AT EDINBURGH.

AN interesting feature of the Pathological Museum at the meeting of the British Medical Association at Edinburgh was a collection of skiagrams which abundantly illustrated the wide range and usefulness of this new aid to diagnosis. Mr. Noble Smith sent a technically excellent series of congenital dislocations of the hip, together with a case of coxa vara, the exact nature of which could be established only by the photograph. Dr. Macintyre of Glasgow showed the transposition of viscera in a youth whose age was not stated. This beautiful photograph, about 16 in. by 24 in., was evidently taken with the patient in the prone position. One interesting point was that the ribs were clearly shown even in front of the liver.

Mr. Lynn Thomas sent eleven instances of Colles's fracture which showed that the styloid process of the ulna is often broken off in that injury. A child's arm with deformity like that of Colles's fracture was found to have a transverse fracture of the radius higher up than the site originally described by that surgeon. This latter point was also clearly brought out by Mr. Griffith Wilkin (London). Mr. Alexander Miles exhibited a characteristic skiagram of a case of double knock-knee which demonstrated how such a photograph of the bones might guide the surgeon before operation. He also showed an example of bad union of a femur fractured below the trochanter which revealed the exact state of affairs with striking effect. Dr. Walsh sent two instructive skiagrams taken in a medico-legal case where an unsuccessful attempt was made to detect an alleged fracture of the ribs over the liver. An aneurysm of the aorta was discovered, however, and a record obtained of extensive bronchiectatic cavities in the lung. Dr. Dawson Turner sent some beautiful stereoscopic Roentgen photographs of the injected blood-vessels of the principal organs of the body. His method is to inject in the ordinary way and then to take Roentgen photographs from different points of view. Either the object or the focus-tube must be displaced laterally in taking the second photograph. He used a displacement of 6·6 inches with the tube 12 inches from the sensitive plate. A Wheatstone stereoscope yielded a remarkable effect in liver, heart, and kidneys. This method would probably yield good results in the case of embedded foreign bodies. Dr. Harry Rainy and Mr. H. J. Stiles sent an excellent series of mercurial injections of the blood-vessels of the human body. These photographs had a distinct educational value and furnished a bird's-eye view of the arterial circulation. The same gentlemen contributed a set of skiagrams illustrating various diseases of bone and showing how, owing to rarefaction or sclerosis, it was possible to define many morbid processes which must have remained doubtful apart from operative interference. A gumma of the ulna showed the irregular erosion of the bone in the centre of the growth and a fresh formation (sclerosing osteitis) at the edges and presented a clear picture of the pathological changes which were taking place. An old Colles's fracture displayed wonderful bone texture and compared favourably with the best work shown at the societies. An interesting case revealed destruction of epiphyses in a child's hand injured by frost-bite. By contrast with the unaffected hand the epiphyses were seen to have gone more or less completely from the base of the first and second thumb phalanges and the base of the first phalanx of the forefinger. An abscess of the calf showed a large diffuse shadow in the substance of a greatly enlarged calf. The soft tissue of the boot came out admirably, so that even the stitches were visible. One remarkable photograph was that of a stunted hand of which the bones were greatly thickened and bossed. The bones of a male dwarf, twenty-three years of age, displayed little advance in ossification over those of a rickety girl ten years of age. A case skiagraphed by Dr. Thompson showed the character of a fracture in the upper part of the tibia, thereby affording valuable indications for treatment. Dr. Steven (Glasgow) exhibited a good and clear photograph of hypertrophic (non-pulmonary) osteo-arthropathy; there was subperiosteal new formation of bone in the radius and the metacarpal bones. Taken as a whole the collection afforded an excellent survey of the present position of Roentgen photography in the world of scientific medicine.

THE LANCET.

LONDON: SATURDAY, AUGUST 27, 1898.

ABOUT three years ago it was announced that Professor BEHRING had applied in the United States for a patent for his "invention" of diphtheria antitoxin, then still on its trial as a therapeutic agent. The medical world at first refused to credit a rumour which pointed to a line of action so contrary to the first principles of scientific ethics and morality. It is the proud boast of the man of science that in all things concerning the health and well-being of humanity his researches are open to the world and that he neither seeks nor expects any other reward for his labours than the approbation of his fellows. But, alas, in these days of commercialism and the love of material riches such rewards as those may seem to be empty though honourable, and as a discovery becomes of value it comes to be regarded as a thing which can be bought and sold, something which can be made to yield a handsome profit provided a monopoly can be obtained for it. This view has hitherto been sternly discountenanced in medicine by all who desire that its practice should be kept free from personal greed, and it was with relief that the medical world learnt of the failure of the application to create an antitoxin monopoly in America. Unhappily, with a persistence worthy of a better cause, this application was repeated again and again, and last week we had the pain to announce that Professor BEHRING had at last gained what he had been so long seeking. We could have wished that he had been convinced by his previous failures of the futility as well as the foolishness of his embarking on a course so repugnant to the ideas which govern medical science. Besides, the claim for such a monopoly seemed on the face of it to be ridiculous, since every detail of the process for which the patent was sought has long been common property. No wonder that there is in the United States the expressed determination to contest the claim to monopoly on the part of those who have been for the past few years engaged in preparing the remedy. The only possible justification for the step would be that Professor BEHRING was so convinced that the process was one too intricate to be properly carried out by anyone else as to render it incumbent on him to prevent the market being flooded with inferior articles likely to bring discredit on the value of his remedy. But no one, not even Professor BEHRING himself, could be rash enough to advance such a plea in defence of his ill-judged action. The mode of preparation of the serum is well known, it is practised with great care in many quarters, and the efficacy of the antitoxins produced from other laboratories than those of the Höchst-Farbwerke has been amply proved. No; we fear that the patenting of the process can bear but one construction—namely, the desire to secure a monopoly in a remedy of proved value for which there will always be a demand. We would fain think that Professor BEHRING himself has had no active part in the proceedings to which his name is attached and that he is not really desirous of exploiting his admirable scientific researches to his own advantage. May not the manufacturing company which undertakes the preparation of the serum under his auspices have been the active party in the business, swayed thereto by the commercial instinct which has nothing in common with pure science? If, however, Professor BEHRING has been more than passive and is indeed responsible for these repeated applications to the United States Patent Office, then we can only express our deep regret that he should have persisted in a course which has no parallel in the annals of scientific medicine. It cannot fail—as indeed has already been the case—to evoke much scrutiny into the precise claims of Professor BEHRING to the discovery of the immunising serum. Such a claim on his part has been styled "preposterous," and it must be confessed that large as has been his share in the work many others have contributed to it, whilst the whole foundation of "artificial immunity" was laid by the genius of PASTEUR. With even more justice might claims have been made for patents for thyroid extracts, not to mention many other remedies which have been freely given to the world by those who first discovered their properties. No one desires to see pharmacology entangled in a maze of monopolies or therapeutics dominated by patent medicines.

The indignation aroused by the granting of this patent was typified in the article in *Pædiatrics* from which we quoted last week. There is before us as we write a similar protest in the leading columns of the *Medical Age* (Michigan) and, indeed, our exchanges show that many medical and pharmaceutical journals in the United States are contributing their quota to the outcry. The *Medical Age* asserts that Professor BEHRING'S "claim to be the exclusive inventor of antitoxin not only indicates a spirit of commercialism which does its possessor no credit, but it displays a disposition to assume credit for the labours of others and to make of these an occasion of personal gain which can only indicate a high degree of moral perversity." This is strong language and yet it is not unmerited, for, according to that journal, the following are Professor BEHRING'S "claims." 1. A process "of producing diphtheria antitoxin, which consists in inoculating horses or other animals capable of being infected with diphtheria with repeated doses of diphtheria poison or living diphtheria bacilli of gradually increasing quantity and strength so as to immunise them and form in the blood a counter-poison for destroying the poison secreted by said bacilli, drawing off the blood from said animals, separating the serum from the blood-corpuscles, and concentrating the former for use as substantially set forth. 2. As a new substance, diphtheria antitoxin, consisting of the concentrated serum of the blood of animals treated with diphtheria poison, and having the characteristic of immunising test animals against infection with diphtheria, and curing them when artificially infected with diphtheria, said serum containing a counter-poison having the property of destroying the poison secreted by the diphtheria bacilli as substantially set forth."

It is difficult to conceive how the United States Patent Office could after repeated refusals have been convinced

Digitized by Google

that the applicants were entitled to be regarded as the sole discoverers of a method which was the outcome of slow and prolonged scientific investigation and reasoning pursued in all directions. Much less can it be understood what fresh facts could have been adduced to cause a change in policy and to create a monopoly in a remedy the production of which has for three or four years been carried on at several centres in the United States. The American critics deplore the laxities of their Patent Office and hint that it would be impossible for similar applications to be entertained in Europe. It is possible that such have been made, or else that advantage has been taken of the greater facilities afforded in the United States for obtaining patents. The pity of it is that any such application should have been made at all. Surely Professor BEHRING never dreamed of taking such a step when he revealed his process and gave it freely to the world. It must have been an afterthought, and it almost bears the appearance of having been deferred until the scientific worth of the discovery had been appraised and the commercial value of the remedy thereby heightened. After all, the award of the patent may prove a hollow triumph; it will be most difficult to determine in the courts as to its infringement and it may well happen that the gains of the monopoly will be illusory.

WE have already commented in part on the lessons of an error of diagnosis at Guy's Hospital in the case of a carman and pointed out how difficult it is in such situations to be always right.[1] The element of alcoholism in hospital cases is so frequent and enters so largely into their causation that the wonder is that such errors do not occur more frequently. But error must be treated as error and we have no wish to make excuses for it. The people have a right to expect at hospitals the elimination of all such risks and our object in returning to the subject is to extract from the case and from an equally significant case which quickly followed still further lessons for our readers' information. The second case was that of a child, of Honbury-road, Nunhead, aged ten years, who was taken to Guy's Hospital on August 10th with an injury to the eye from a piece of wood which had pierced it. He was not admitted, but Mr. STOEHR, a dresser, instructed the mother to bring the child to see him the next day at a quarter-past one. Then some unexplained misunderstanding occurred. The mother on the next day could not find Mr. STOEHR; Mr. STOEHR could not find the mother. The accounts given in the press and at the inquest do not allege the same reason for their having missed each other in the waiting-room at the hospital. The child was kept waiting and before admission had some sort of convulsive seizure. On the next day he died from meningitis, the initial injury having been of a far more serious nature than the dresser had been able to detect.

The people, we say, have a right to expect at hospitals the completest elimination of the chances of error which is possible. In such institutions there is, or there ought to be, the fullest convenience for checking errors. The accommodation for detaining cases should be complete. Twelve hours' detention would in itself be a great security against confounding fracture of the skull with mere alcoholism. In the case of the unfortunate carman such detention would have been sufficient to clear up the diagnosis, though it might not, and properly would not, have altered the sequence of events. Moreover, a hospital is supposed to be a place where in the multitude of counsellors there is safety. One resident medical officer may be gifted with more caution or more insight than another, and in all difficult cases the staff ought to be available for purposes of reference. It is creditable to the medical staff that at Guy's Hospital a severe tradition still insisted on by its surgeons requires the assistant surgeons to sleep in the hospital during their week of office, so that they are as ready to give counsel by night as by day. The fact that these cases have occurred in an institution so well governed as Guy's Hospital, in which the severe tradition to which we have referred obtains, only makes the lessons to be learned of prudence and circumspection more significant. To us it seems that these errors form only another illustration of the great abuse of hospitals which it is our weekly duty to expose and denounce. Treatment in hospitals may become hurried and hasty because the public will persist in attending for the gratuitous treatment of petty ailments. The really grave cases for which hospitals primarily and almost exclusively are meant are elbowed out by hundreds of cases which might just as well be treated at home by general practitioners. If once we could bring back hospitals to their primary use and restrict their services to the really necessitous as well as to grave cases which cannot receive proper nursing or adequate professional attendance at home we should do much to prevent these regularly recurring catastrophes. It is quite probable that both the patients whose stories have recently received such public notice would have fared better (possibly the result of one of the injuries might have been different, as the coroner suggested), if the patients had been kept at home and treated by the nearest practitioner. The fruitless and jolting journeys, the loss of time and the waiting, would all have been avoided. We hope that the authorities of Guy's Hospital will take in good part our implied suggestion that the great evil of hospital abuse may have been at the bottom of the errors of judgment. All friends of hospitals must rejoice that the governors of Guy's Hospital are beginning to realise recovery from the cares of hard times and attenuated income; but they will rejoice more if the governors will set an example to other hospitals of attempting to deal seriously with the admitted evils of indiscriminate hospital relief to all and sundry applicants so as to leave time and leisure for serious cases.

If any doubt is felt as to the urgency of these evils it must be removed by the universal feeling of the profession on the subject. At the recent meeting of the British Medical Association in Edinburgh various papers, an abstract of which we publish to-day, were read under the auspices of the Hospital Reform Association. Mr. GARRETT HORDER in his paper gives particulars of the out-patient system in Scotland. He shows that it threatens to assume in the north the same evil proportions as in England and

[1] We may add that we have since received from the house surgeon a very explicit statement of the matter, in which the difficulties revealed ully justify the extension to him of all sympathy.

Digitized by Google

that there is a slowness in that provident division of the kingdom to guard against the subtle evils of hospital abuse. In Edinburgh alone the out-patients number 109,141. It is not credible that the great working-classes of the Kingdom whose trade organisation is so evident and so efficient, will think the less of the medical profession for organising itself for the vindication of its just claims or that they will always ask to obtain their ordinary medical attendance either gratis at hospitals or at the cost of medical men working night and day for the wages of farm servants. The really bad cases which require hospital treatment will be better cared for when the thousands of ordinary cases have been eliminated from the hospital out-patient department. The occurrence of such errors as those on which we have commented and which do great harm to our hospital system will then be much less frequent. One point was well brought out at the meeting of the Hospital Reform Association in Edinburgh, and that is the importance of the coöperation of the medical staffs with the general practitioners of the country. Their interests in the long run must be identical, and the sooner each class appreciates this the better for both.

THE unfortunate community supplied with water by the East London Waterworks Company are again undergoing the terrors of a water famine. Since the droughts of the summers of 1895 and 1896 the East London Waterworks Company have added considerably, we may say enormously, to their storage capacity. The Warwick East Reservoir, which was completed in May of last year, has an area at the top of the water-level of forty-five acres. The top of the water-level is 35·60 ft. above Ordnance datum and the reservoir is capable of holding 210,248,000 gallons of water. We probably do not exaggerate in stating that the storage capacity of the company is equal to over 1,000,000,000 gallons, while the necessary powers for further developments have been obtained. But although there is such excellent capacity for containing, contents are sadly wanted. By the end of last week only a seventh part of the possible storage was in hand, and now the regular supply has broken down. On Monday last the company announced to its clients that the water would be turned on for six hours *per diem* only and, to add to the inconvenience of these luckless people, gave them no full intimation of the hours during which the supply for the intervening periods might be drawn and, if their complaints may be believed, failed to ensure regularity in the delivery of the intermittent supply. We sympathise deeply with the clients of the East London Waterworks Company in the extreme discomfort which is thus entailed upon them, and must also point out that the matter is one of urgent importance to all the metropolis because of its sanitary bearing.

A letter in the *Times* of Wednesday last signed by twelve medical men practising in Ilford, one of the districts within the area supplied by the company, draws attention to the gravity of the situation with which they find themselves confronted. "We have already," writes Mr. MURTAUGH HOUGHTON and his co-signatories, "in our respective practices numerous cases of diarrhœa, and the proportion of these will no doubt enormously increase, nor apparently will the water company be content until they have been directly responsible for some hundreds at least of deaths both among adults and infants, for in our opinion the stoppage of the water-supply will as directly cause their deaths as if the patients had been actually poisoned." This, of course, is very strong language, but we doubt if it is in excess of the truth, save where the words imply that the company is actually striving to bring about the serious consequences which the medical men of Ilford predict. The company of course does not desire to be short of water; it does not work to bring itself into its present discreditable position. On the contrary, the officials of the company with the chief engineer at their head have made very strenuous efforts to alleviate the troubles of their *clientèle*. They have arranged with the Hackney Vestry for a house-to-house delivery of water by carts supplied by the vestry at the company's expense. This water is delivered free during the hours when the company's water is turned off and all persons failing to secure a supply are requested to communicate in writing with the Hackney Vestry, which body is doing admirable service to the public and deserves great credit for its energy and promptitude. The company has promised to attend at once to all requests made to it from hospitals and similar institutions and to do its utmost to guarantee that the work of such places will be carried on without the additional risk of a scanty water-supply. Stand-pipes have been erected in many of the most crowded districts of the company's area, to which the people can go with jugs and other receptacles to secure some small supply to keep in their houses. All these things the company have done, but the total inefficacy of such makeshift methods to cope with the mischief of a water famine need not be dwelt upon; nor does the company appear yet to have done all that is possible in its sad situation. We are told that the New River Company and the Kent Company will provide the East London Waterworks with an auxiliary supply. But readers of THE LANCET, by consulting the articles of our Special Commissioner published in our columns last year, will see that the East London Waterworks Company should be able to receive, through its Thames intake, assistance from at least two other companies. Has this assistance been applied for yet? And if not, why not?

The question of the water-supply of London is an exceedingly difficult one, and whoever should rashly draw general deductions from any small collection of facts would risk deceiving his hearers and writing himself down an injudicious person. Therefore we do not follow in the suit of those who claim that the condition of things in the North-east of London by itself absolutely condemns our present metropolitan water-supply in its source, its management, its conduct, its engineering, and its morals. The harm which has actually been done so far is, we believe, not very great, and the efforts of the company may avail to see that it does not become greater, while the drought this season has been extraordinarily persistent and should not be regarded as conforming to normal English weather. But there is no denying that this, the third consecutive water famine which has occurred in a part of the metropolis

Digitized by Google

largely occupied by a crowded and poverty-stricken populace, furnishes a more convincing piece of evidence as to the necessity for reinforcing the water-supply of London as a whole than all the evidence which has yet been taken before Royal Commissions or than ever will be taken. The mid-summer relations between the East London Waterworks Company and the denizens of East London form an argument that is at any rate specious for the amalgamation of the companies under one authority, so that those with ample storage could come to the aid of their depleted brethren; while the same relations go far to justify the princely scheme of the London County Council for creating reservoirs of boundless capacity in the Welsh valleys.

Annotations.

"Ne quid nimis."

THE HEALTH OF THE PRINCE OF WALES.

WE are pleased to learn on the best authority that during the past fortnight the progress made by H.R.H the Prince of Wales has been very gratifying to his surgeons. Indeed, during the five weeks and a few days which have now elapsed since the accident nothing has occurred to interrupt the progress of the case. The local conditions are all satisfactory. There is but slight effusion remaining in the joint and but limited swelling in the surrounding parts. The fragments are maintained in close apposition, the amount of separation not exceeding a quarter of an inch, and the progress of union is proceeding in the ordinary way. Gentle massage has been daily practised with much advantage to the muscular tone and general nutrition of the limb, and recently slight passive movements of the joint itself have been accomplished without any pain or inconvenience. The upper fragment is kept under complete control during these movements, no undue stress is put upon it, and it shows no sign of yielding—a condition of things which augurs well for the future mobility of the joint. It is not possible of course at so early a date to say with precision how far the motion in the limb will be completely recovered, but every possible precaution against mishap will of course be taken. His Royal Highness has left Cowes for a cruise in the Channel and will visit Portland, Plymouth, Dartmouth, and perhaps other places. It is hoped that at some of these he may obtain carriage exercise, which would prove an agreeable and beneficial change. Four of the sailors on board the *Osborne* have been thoroughly drilled as a carrying party and so perfectly do they perform their duty that there need be no apprehension of accident when they are transporting His Royal Highness ashore. In two or three weeks' time a specially-made check splint will probably be worn in which the amount of knee flexion can be exactly controlled and the lack of extension power on the part of the quadriceps extensor compensated for by a spring apparatus. In this apparatus the patient will be able to walk, at first with the assistance of crutches and later with a stick. The Prince is fully aware of the long interval which must ensue before the repair of the injury he has so unfortunately sustained is thoroughly accomplished and is quite prepared to submit to all the restrictions which the need for incessant care entails. The fortitude, good temper, and patience that he has shown under circumstances so trying are admirable, and we feel sure he possesses the sincerest good wishes and sympathy of the entire community.

THE QUALIFICATIONS OF PUBLIC ANALYSTS.

FOR many years past the Local Government Board have only approved of an appointment to the post of public analyst on condition that the person nominated supplied documentary evidence to the effect that he was properly qualified in analytical chemistry and that he possessed such microscopical and therapeutical knowledge as was obviously necessary for the purposes of an Act dealing with the sale of foods and drugs. Thus, in the absence of the possession of a qualification in medicine the candidate has always been required to supply evidence signed by some authorised person to the effect that he possesses sufficient knowledge in microscopy and therapeutics to enable him to perform the duties of a public analyst; whilst, on the other hand, no registered medical practitioner has been accepted who did not produce separate evidence of his competency in analytical chemistry. We refer to this subject on the present occasion because of the issue of a circular by the Institute of Chemistry of Great Britain and Ireland which announces in the first place that the qualifications of the Institute are accepted as satisfactory by the Local Government Board in so far as chemistry is concerned; and, in the second place, that the Institute have decided to establish an examination for their Fellows and Associates which shall afford proof that they likewise possess the necessary knowledge in therapeutics, pharmacology, and microscopy. The announcement is satisfactory, for it must clearly be an advantage to all concerned to find in one single qualification evidence of the possession of all the necessary requirements. The circular issued by the Institute does not, of course, announce that the result which they desire to attain has already been achieved; indeed, it is clear that the Local Government Board could not in advance say of an examination which does not come into existence until October next that it will meet all their requirements. But it is equally clear that if the examination conducted by the Institute in therapeutics, pharmacology, and microscopy is of the same standard as that which has obtained official sanction in regard to chemistry the certificate of having passed the additional examination is likely to be regarded as affording evidence of competency in the subjects other than chemistry; and in this way it will be a distinct advantage to Fellows and Associates of the Institute seeking the post of public analyst. With a view to this end the Institute will probably bring under the notice of the Local Government Board such evidence as to the character, scope and standard of the new examination as will enable that Board to judge whether it fully meets their requirements. But even if it does so the possession of this special certificate or diploma will in no way be the only portal to the post of public analyst. Every medical practitioner who has sufficient competency in chemistry will be equally eligible, provided his other duties do not prevent him from that systematic laboratory attendance which is essential to the due performance of the duties of a public analyst. Apart from this consideration we are of opinion that a medical training combined with a good knowledge of analytical chemistry affords the highest evidences of fitness for the post of a public analyst.

THE SMOKE NUISANCE.

WE reproduce the following sentences which appeared in an annotation on the above subject in the columns of THE LANCET of July 9th, 1898: "The nuisance has doubtless been accentuated by the fact of the Welsh strike, Welsh coal being a hard, brittle coal, which burns without much smoke. But, as we have already pointed out, the clause in the Public Health Act was obviously aimed at securing certain structural arrangements of the furnace

Digitized by Google

or fireplace which would deal with smoky coal. A deliberate evasion of the requirements of the Act is admitted, therefore, it seems to us, by those who plead in defence that the nuisance was created in consequence of the inability to get smokeless coal. In other words, now that only smoky fuel can be obtained the furnaces are found to be in fault and it has remained for the Welsh strike to bring this fact to light. ..... The electric lighting stations in the metropolis are amongst the worst offenders. We trust that we shall continue to hear of the unabated efforts of our sanitary authorities to suppress a nuisance for the continuance of which there is not a shadow of excuse." On August 4th the Metropolitan Electric Supply Company was summoned for causing a nuisance by allowing black smoke to be emitted from their chimney; also for using furnaces so constructed as not to consume their smoke, and also for using the furnaces negligently so that the smoke was not consumed. The case was adjourned to enable the magistrate, Mr. Hannay, to give a deliberate decision, the defence being the same story of being unable to get Welsh coal. After expressing the opinion that an offence had been committed this is what Mr. Hannay said: "I have no hesitation in saying that it is monstrous to urge, as has been urged in effect before me and other magistrates, that the metropolis of this country must continue smothered in smoke until the Welsh miners and their employers have settled their differences. My past experience convinces me that the smoke nuisance can be kept within reasonable bounds if the authorities only do their duty. It may cost the manufacturers something more to have their furnaces properly constructed and well attended to, but that is as nothing compared with the injury and damage caused to the general public by the reckless fouling of air which has long been going on unchecked." This is complete confirmation of the opinions which we have expressed again and again in THE LANCET and our view on the interpretation of the law upon the subject is thus emphatically endorsed by a well-known legal authority. We trust that this pronouncement will encourage our health authorities to persevere in the crusade against the wanton befoulment of London's atmosphere and lead to a permanent suppression of the intolerable nuisance.

THE STAGES AND FORMS OF SYPHILIS.

PROFESSOR J. G. ADAMI has an interesting article in the *Montreal Medical Journal* for June entitled "On the Stages and Forms of Syphilis, with more especial reference to the Hepatic Manifestations of the Disease." He commences by suggesting that it is remarkable how during past centuries syphilis has remained sharply distinguished from all other forms of human disease, constituting a class apart. He then draws attention to the fact that from the time of Ricord primary, secondary, and tertiary stages have been clearly distinguished, and not only this, but according as to whether the disease is acquired in post-natal life or has seized upon the individual while *in utero* so do we recognise two different types of the disease. With reference to these points Professor Adami lays down (1) that from analogy as from clinical history and absence of any indications of the same in sundry cases there may be an absence of the primary, cutaneous, or epithelial manifestations of syphilis; (2) that individuals may fail to present either primary or secondary symptoms which are recognisable and yet eventually develop definite tertiary lesions of the disease; and (3) that where the subject is relatively insusceptible it is possible that the disease may be limited to the primary cutaneous manifestation not followed by secondary lesions. The whole of this paper is of considerable interest, but we have only space for a brief summary. Professor Adami demonstrates that the lesions occurring in the congenital and acquired disease are identical and brought about by the same process or processes; that whether we have to deal with the disease in the secondary or in the tertiary stage the same processes are at work; and that, if we except those cases as truly tertiary in which we have to deal merely with the fibroid remains of absolute gummata and again those cases in which there is perihepatitis (which perihepatitis appears to be a complication rather than the genuine and direct result of syphilis), then we are bound to admit that the study of the liver alone would indicate that no sharp boundary line can be made out between secondary and tertiary syphilis. This is true anatomically and histologically—i.e., that there is no valid distinction to be drawn between secondary and tertiary syphilis. It may be asked, says Professor Adami, whether such a conclusion is not wholly at variance with clinical opinion and experience. Upon the face of it it is, but if the subject be looked at carefully he thinks that such a view will reconcile not a few of the divergencies existing among writers. "We have those (and they are the majority) who state that tertiary syphilis is non-infectious and those who bring forward clear examples of the production of infection five or ten years after primary inoculation of the disease. This difference can be reconciled if we agree upon the following points. 1. That under proper treatment syphilis, if not a self-limiting disease, is at least a disease which can be healed, so that many of the lesions recognised as being tertiary syphilis are truly the indications of the old healed syphilis and not signs of progressive or latent disease. 2. If the disease has not completely died out and remains latent the resistance of the tissues of the organisms is such that in the majority of cases if it does not tend to light up again there is so considerable a local reaction that the infection and consequently the spread of the process tend to remain strictly localised, and the germs (which are probably of bacillary nature) do not become disseminated through the blood. Thus neither the blood nor the secretions contain the virus. 3. In a very small number of cases, the reaction on the part of the tissues may be so lessened and the virus retain or gain so high a virulence that either it causes ulceration or in other ways becomes disseminated and capable of causing infection even later in the tertiary stage."

THE ADULTERATION OF CHAMPAGNE.

IT is at any rate a redeeming feature in these days that adulteration generally occurs in some wholesome form. For all that of course it is still a fraud, the public are swindled, but not poisoned thereby. Sophistication, in short, commonly amounts now to substitution. Margarine is an excellent food substance, but it is not butter; the potato is an excellent food also, but it should not be found in bread; and wheaten flour is good, but the fact of colouring it with turmeric does not make it mustard. Gooseberry wine, again, is an excellent beverage, but it cannot with the smallest degree of truth be called champagne, even though the name has been accepted for years by the public as a synonym for cheap champagne. We are inclined to doubt whether the gooseberry to any great extent was ever made to replace the grape in the way indicated. Lord Palmerston, it is said, once told a deputation of wine merchants who waited on him that there was never a good champagne year in France unless there was a good apple crop in Normandy. We should like to think that this was because the season which was favourable to the production of good grapes was also favourable to the production of good apples. It is also stated that many owners of large pear orchards in France are under contract to send their

Digitized by Google

entire produce to a firm of wine merchants in the champagne district. It is evident, if this be true, that a large section of the public is beguiled into regarding cider, perry, and gooseberry wine as champagne. In other words, pears, apples, and gooseberries evidently afford abundant material for making a very popular, excellent, and palatable drink. In spite of this fact people are constantly asking the question, What shall we drink? But really good cider, perry, and gooseberry wine are not easy to procure except in the immediate neighbourhood of their production, as in Herefordshire, Devonshire, Somersetshire, and Norfolk. Perhaps, then, the proper names of these estimable beverages are not high-sounding enough. Under the falsely described and tempting title of champagne, however, the public eagerly drinks, smacks its lips, and says, "An excellent wine." And thus the immoral traffic in substitution is encouraged and sustained to the enormous profit of the dealer and greatly to the detriment of the purse of the consumer. It affords another instance of the public preferring, it would seem, to go on being gulled.

LOCUM TENENTS.

THE demand for locum tenents in the present season is said to be very great. At some hospitals it has been found impossible to meet the demand. This fact accords with the testimony of many correspondents as to the difficulty of getting qualified assistants and is doubtless largely to be explained in the same way. The action of the General Medical Council in requiring all responsible medical work to be done either by the principal or by a qualified assistant has added to the value of the qualified man as a locum tenent. It has probably also added to the financial value of such functionaries. It is to be hoped that the unusual demand for locum tenents is also partly to be explained by the fact of a greater number of medical practitioners taking a reasonable holiday. It would seem that there is a considerable number of medical men who never take a real holiday. An illness or an accident may suspend their work for a few weeks, but they never take a formal holiday of any length or only at an interval of several years. When holiday-taking has become almost universal this exception is remarkable and significant. Let us hope that without going to the other extreme of restlessness, which is too common, the members of our profession will recognise the wisdom of making an annual break of at least a fortnight in the prosecution of their arduous and exacting work.

INSANITARY AREAS IN BRADFORD.

IN May, 1897, the Sanitary Committee of the Corporation of Bradford adopted a report by the sub-committee on insanitary areas in which there was a recommendation that certain districts should be dealt with under the provisions of the Housing of the Working Classes Act. The medical officer of health, Dr. W. Arnold Evans, has made a representation to the committee concerning the question to the following effect: the district contains 7 streets and parts of 4 others and the total area is 22,650 square yards. It contains 284 houses with a population of 1357, the density of population being 301 persons per acre, as against 21 persons per acre for the whole city. The death-rate from all causes in this area has been, per 1000, in 1895, 45·6; in 1896, 42·7; and in 1897, 41·2. Dr. Evans divides the area into two parts, the first of which contains Longlands-street, Long-croft-place, Garden-place, and the north-east side of Chain-street. The remainder of the area is much less insanitary and in the opinion of the medical officer can be dealt with by the improving of certain single houses. But the first-named area is too bad for this and must be dealt with by an improvement scheme. Longlands-street contains a population of 386 with an average of people per house of 5·5, the closet accommodation being very sparse; the average of people per closet is 15. The death-rate for the street in 1896 was 69·9 per 1000, but in 1897 it sank to 36·2 per 1000. In Longcroft-place live 466 people, being 4·2 persons per house; the average of persons per closet is 9·9. Five of the houses in this delectable neighbourhood are cellar dwellings, one of which is used as a muffin bakery. Garden-place and Chain-street present much the same conditions. An analysis of air gave the following results: in air from Longcroft-place on a still day with temperature 71·5° F. there were found 6·6 parts of CO_2 per 10,000; air taken from a tenement house gave 8·8 parts of CO_2 per 10,000. We have little doubt but that the Corporation of Bradford will carry out the advice given by their medical officer of health, but we hope they will take care of one thing. It is generally found that in cases of "improvement" the improved dwellings are let at rents which are far too high for the dispossessed workers to pay; consequently they herd into, if possible, still more insanitary dens than the ones from which they have been ejected. Municipal enterprise has to step in in most cases if bad is not to be made worse.

A MICRO-CHEMICAL TEST FOR PHOSPHORUS.

PROFESSOR MACALLUM, in a paper recently contributed to the Proceedings (page 467) of the Royal Society, describes a method by which the phospho-molybdate test may be used with success for the detection of phosphorus in animal and vegetable tissues. He finds that the indefinite reaction given by the direct application of the test owing to the colourless character of the phospho-molybdate precipitate when occurring in the tissues or in the presence of a reducing agent (unless that agent be carefully chosen) may be avoided by the use of phenyl-hydrazine hydrochloride as the reducing reagent, which produces a green colour whenever the phospho-molybdate precipitate has been formed. The brown colour produced by the molybdate alone does not interfere with this reaction. Tissues which have been hardened in alcohol are the best for this treatment. The preparations were washed (after treatment), dehydrated, and mounted in the usual way. The paper concludes with an account of a demonstration by means of this method of the presence or absence of phosphorus in the various cell elements of diverse animal and vegetable tissues.

FOOD PRESERVATIVES.

CONSIDERABLE contention has waged round the legality or desirability of employing preservatives in perishable articles of food and the subject naturally comes to the front during a spell of hot weather such as that which we have been experiencing for the past three weeks. There is little doubt that some means of preserving food are absolutely necessary when the prevailing conditions are such as to "turn" food in a few hours. Otherwise milk, cream, meat, &c., become unfit for consumption, unpalatable and evil-tasting. To keep the articles somewhere near freezing point is obviously impracticable on any large scale, while sterilisation is similarly beyond application. This reduces our resources to the simplest of all expedients, the addition of an antiseptic in such quantity as to preserve, at any rate for a time, the article from objectionable change and yet in minimum quantity so as not to constitute a possibly harmful amount. We think the use in limited quantities of such mild antiseptics as borax to be justified at a time like the present when otherwise a considerable amount of valuable food substances would be wasted and lost. But, as we have urged before, the fact of an article being thus preserved against change should be always notified to the consumer, and we would have limits imposed by the State as to the amount of the preservative to be used; moreover, the nature of the preservative should also be declared. In other words, we would establish a system, recognised by the State, by which under

Digitized by Google

certain circumstances the employment of preservatives with restrictions as to their nature and amount could be legalised. This is a view which we have expressed before and notably in the report of THE LANCET Special Sanitary Commission on the Use of Antiseptics in Food which was published in THE LANCET of Jan. 2nd, 1897. In that report were also embodied the views of several medical men who are accepted authorities on food questions. Quite recently we have received an important contribution on the subject by no less an authority than Professor Chittenden of Yale University. As the result of a series of very interesting experiments this physiologist reports that the results would appear to warrant the statement that in particular boric acid and borax when present in moderate quantities can have little or no deleterious effect upon the more important chemical processes of digestion. On the contrary it would appear that the presence of these agents may, in some cases at least, even accelerate the normal digestive processes of the alimentary tract. In regard to the effects of borax and boric acid on nutrition the same observer concludes that when borax is given in sufficient quantity to produce any effect its action is similar to that of common salt—i.e., it tends to increase proteid decomposition. Both borax and boric acid, he states, are without influence upon the putrefactive processes of the intestine, apparently because of their rapid absorption from the intestinal tract and quick elimination through the urine.

SERO-THERAPY IN NEOPLASMS.

AN article with this heading by M. C. Beretta appears in M. Richet's "Travaux du Laboratoire," the fourth volume of which has just been published. Two years ago MM. Richet and Héricourt communicated to the Académie des Sciences two cases which were extraordinarily successful and which seemed to show that *sometimes* cases of fibro-sarcoma might be cured, or at least benefited, by the injection of anti-cancerous serum. The mode of obtaining the serum was to reduce the cancerous tumour with antiseptic precautions to a pulp with powdered glass, to add distilled water, filter, and then by centrifugation separate the fluid into three portions, an upper layer consisting of emulsionised fat, a second layer of the cancerous juice, and a third layer of the organic débris and glass-powder employed. The juice thus obtained is an opaque, greyish-red liquid, exhibiting when examined under the microscope many more or less broken-up cells, white and red blood corpuscles, fat drops, fibrin, and a deposit of granules rich in nuclear particles. Micro-organisms are also visible which either proceed from the tumour itself or possibly from the air which has been in contact with the fluid during the manipulations. The animals used in M. Beretta's experiments have been the horse, the ass, and more particularly the dog, the cancerous juice being slowly injected into the vein of the foot in the case of the dog, into the nasal vein in that of the horse, and into the marginal vein of the ear in that of the ass. The quantity injected was in proportion to the size of the animal—from 20 to 40 c.c. in the case of the horse, from 10 to 20 c.c. in that of the ass, and from 5 to 10 c.c. in that of the dog. These inoculations were repeated from month to month, each injection being better borne than the last, as if a kind of toleration were established for the cancerous juice. At the end of a certain period the animal was bled in order to obtain the anti-cancerous serum. In the case of the horse and the ass 1 or 2 litres of blood were taken, but in the case of the dog the animal was sacrificed and the whole of its blood was collected and the serum obtained with the usual antiseptic precautions. The mode of using it was almost always by hypodermic injection at some distance from the seat of the disease. In some instances no benefit was observed, the patients became discouraged, and no further trial of the remedy was made. In other instances pain was notably diminished and the volume of the tumour underwent reduction, and it is to be observed that all the cases were taken in hand at a late period of the disease, the cachexia being well established. M. Beretta has collected no fewer than seventy-three cases, of many of which he gives the details, in which this plan of treatment has been followed by more or less success. Amongst these are cases of atrophic scirrhus of the breast, of cystic tumour of the breast, of ulcerated tumour and of cancer of the base of the tongue, of cancer of the rectum, stomach, and uterus, and of degenerated naso-pharyngeal polypus. The general results of M. Beretta's experiments and observations may be regarded from a physiological and pathological and from a clinical point of view. From the physio-pathological standpoint it would appear that anti-cancerous serum exerts a stimulating influence on the organism, rendering the circulation active and improving the general nutrition of the body. Its employment does not give rise to any special disturbance of the economy, though like all therapeutic serums it may occasion inflammatory troubles, such as redness, eruptions, painful swellings, fever, and more rarely phenomena of intolerance and toxic action. It induces at the seat of the disease a special influence accompanied by more or less lively inflammatory symptoms—which, however, are often altogether absent—which lead rapidly to softening and reduction in size of tumours and of the affected ganglions. From the very outset of these changes and as a consequence of the cessation of nervous and vascular compression, pain, spasms, œdema and hæmorrhages diminish or disappear. The functions of the body, and with this the general health, are improved. At a later period the work of reparation in ulcerated parts becomes more marked, the neoplastic outgrowths, tissue, and necrosed portions are sometimes thrown off, the aspect of wounds improves, and circulation may proceed to a considerable extent. But this anti-neoplasmic influence does not prevent new generations of specific elements from developing in opposition to the action of the serum, and this action seems to be soon exhausted, probably owing to tolerance of the cells. It is rare that the serum is wholly inoperative, but when all good effects have ceased, after an interval of some weeks a new series of injections will sometimes prove serviceable. It has not been proved up to the present time that the use of the serum after an operation can prevent a relapse, but it is a question whether it may not retard one. Anti-cancerous serum has produced similar effects in the most diverse forms of neoplastic growths. M. Beretta is not satisfied that its action is really specific, seeing that normal serum produces similar though less marked effects. From a clinical point of view it may be said that no unquestionable case of cancer in which a cure has been effected has been reported, but it is certainly useful in controlling such symptoms as pain, œdema, and hæmorrhage, in reducing the size of tumours and in improving the aspect of ulcers.

INSECT STINGS.

THE fact of death occasionally resulting from the sting of insects such as bees and wasps is no doubt largely responsible for the species of terror which the presence of these insects brings upon many persons. Only this week, for example, a case was reported of a labourer who placed in his mouth a gooseberry which proved to contain a wasp. The wasp stung him at the "root of the tongue; he went into his cottage, and medical aid was summoned, but death ensued in five minutes." In this instance, of course, death most probably supervened on suffocation due to intense swelling in the throat and was not due directly to the poison itself.

Digitized by Google

Vomiting, fainting, delirium, and stupor strongly suggest a highly virulent substance of the nature of a toxin. The precise nature of the poison of wasps and bees is not known. They possess a poison bag and sting and the fluid secreted is as clear as water, exhibits an acid reaction, and, in fact, contains formic acid. But this acid can hardly account for the severity of the symptoms sometimes following a sting. Fatal results have, indeed, occurred which could only be attributed directly to the toxic action of the sting. Some persons, however, endure the sting with impunity, others develop alarming symptoms, such as blood poisoning, and undoubtedly the toxicity of the sting depends very much upon the condition of the "soil" into which it is implanted. One of the old-fashioned remedies, and we believe a good one, is to apply immediately to the part stung the juice of a raw onion. The *rationale* of this remedy is not clear, the sulphur oil in the onion possibly serving as a palliative. The sting, at any rate, if it remains in the wound, should be extracted and the puncture dressed with a little weak ammonia and afterwards a little bromide of ammonia may be added, which frequently serves as a sedative. Judging from the great number of wasps which have somewhat suddenly appeared in the country during the recent hot weather this seasonal pest promises to be of no small dimensions. The intense irritation caused in some persons by mosquito "bites" may be promptly relieved by the application of ipecacuanha, either the "vinum" or the powdered root, made into a paste with water or vinegar, being used.

JAUNDICE IN TYPHOID FEVER.

JAUNDICE is a very rare complication of typhoid fever. Murchison saw it in only four cases, but some observers have met it more frequently; Griesinger noted it in 10 of 600 cases and Liebermeister mentions that in the Basle Hospital it occurred 26 times in 1420 cases (1 in about 55). The *American Journal of Medical Sciences* for July, 1898, contains an exhaustive paper by Dr. Da Costa, based on 5 cases observed by him and on those previously recorded, making 52 in all. Jaundice does not generally come on until the middle of, or until late in, the disease. But in one of Dr. Da Costa's cases (so far unique) it appeared during the incubation period; in a case recorded by Andral it appeared on the third day; in one by Frerich on the fifth; in one by Murchison on the sixth day of a relapse; in one by Osler on the fourth day of a relapse; and in one by Sorel during convalescence. The stools are much like the ordinary typhoid or darker and greenish, very rarely clay-coloured. The liver is usually tender, especially at its lower border, and may be slightly enlarged. Parotitis has been observed in a number of cases and is not a mere coincidence, which bears out Mr. Stephen Paget's doctrine of a connexion between parotitis and abdominal disease. The liver when carefully examined shows granular or fatty degeneration; sometimes there is abscess (but typhoid abscess is not usually accompanied by jaundice); and sometimes there is pylephlebitis. The jaundice is usually of the toxæmic form and seldom depends on catarrhal obstruction (in the ordinary sense of the term). The prognosis is grave: 33 deaths occurred in the 52 cases. Atrophic cirrhosis was a sequel in one case. Hölscher's statistics of 2000 fatal cases of typhoid fever at the Munich Pathological Institute are instructive. Of 227 in which the liver or gall-bladder were involved there were 203 cases of disease of liver structure, 12 of abscess, 3 of acute yellow atrophy, 1 of amyloid degeneration, 5 of diphtheritic process or suppuration in the gall-bladder, 3 of œdema of the gall-bladder, while 22 are classed simply as jaundice without organic disease. The ordinary parenchymatous changes, not to be recognised clinically, presumably are represented by the 203 cases. Of 22 cases of typhoid abscess of the liver collected by Da Costa only 7 had jaundice. In typhoid fever[1] disease of the gall-bladder is more common than disease of the liver. Jaundice is not a frequent symptom in cholecystitis; it is mentioned in 17 out of 58 cases.

DRINK-FETCHING BY CHILDREN.

AT a recent meeting of the Manchester city justices it wa stated by the chairman of the licensing committee that where extensions of premises were made the committee had for several years stipulated that the drinking accommodation should not be increased and that a "private apartment" should be provided for children sent for their parents' drink, "so that they would not see and hear what was going on in other parts of the house." As drinking habits are in many cases acquired very early in life, and as the temptation to sip a little of the beverage which their parents find so indispensable is to many of the children irresistible, perhaps the magistrates will see that some one accompanies them from the public house to their homes so as to guard them from this danger. Some of the publicans who give sweets and presents to the beer-fetching children might spend their money in this more truly benevolent fashion.

PALPATION OF THE KIDNEY.

THE accessibility of the kidney to palpation is discussed at considerable length by Dr. Wolf Becher and Dr. Rudolf Lennhoff in the *Deutsche Medicinische Woohenschrift* of August 11th. They commence with the remark that during the last fifteen years it has been recognised that the kidney may occasionally follow the rise and fall of the diaphragm during respiration and may in this way admit of palpation without the case being one of moveable kidney in the ordinary sense. An exhibition, including a party of 24 Samoan women, visited Berlin in October, 1895, and afforded an opportunity for the investigation of the question whether any considerable influence on the position and displacement of the kidneys of females was brought about by the wearing of stays and the use of waist-bands for the support of the skirts. Almost all these Samoans had finely-developed figures. Their height varied from 57 in. to 70 in., the average being 65 in.; their chest measurement close under the armpits during expiration varied from 32 in. to 38 in., the average being 35 in.; their ages were from thirteen to twenty-six years. Their clothing consisted of a jacket and apron, which were fastened without any constriction of the waist; none of them had ever worn stays. In 6 of these 24 women the right kidney could be felt; 2 of the 6 had had one child each; in none of them had the kidney any passive motion apart from the respiratory displacement. It is therefore evident that the kidney may admit of palpation and may follow the respiratory movements quite independently of the habitual constriction of the waist by clothing. Of the other women 2 had had one child each and a third had had three children; their abdominal walls were very relaxed but their kidneys could not be felt. From observations made on hundreds of cases in Dr. Litten's poliklinik Dr. Becher and Dr. Lennhoff have come to the conclusion that palpation of the kidney is feasible much more frequently than used to be supposed, and that it is possible before examination, merely from inspection of the shape and conformation of the individual, to predict with a considerable approach to accuracy whether the kidney is accessible to palpation or not. The persons whose kidneys may be felt have usually a slender, graceful figure, long, narrow thorax, and a somewhat flattened, laterally retracted abdomen. Dr. Becher and Dr. Lennhoff

[1] THE LANCET, July 9th, 1898.

Digitized by Google

also devised the following formula for the purpose of obtaining numerical expressions: the length from the supra-sternal notch to the upper border of the symphysis pubis is divided by the shortest girth of the waist and the quotient is multiplied by 100. In the 24 Samoan women this number averaged 75; for the 6 whose kidneys could be felt it was respectively, 69, 75, 78, 83, 83, and 91; while for the 18 whose kidneys could not be felt it averaged 73. With German women it was usually found that if the number was 77 or upwards the kidneys could be felt, but if it was less than 77 they could not be felt.

PHARMACOLOGY AT CAMBRIDGE UNIVERSITY.

CONSIDERING the few years that have elapsed since the Pharmacological Laboratory at Cambridge was established it may be congratuated on its success. In the main this is due to the investigations of Professor Bradbury and his assistant, Mr. Marshall; but the teaching in this department also seems likely to contribute to its reputation as a school. Thus one of the two gold medals awarded by the University of Edinburgh this year for the M.D. theses has been secured by Dr. Andrew Balfour for work done in the laboratory and the gold medal and exhibition at the Intermediate (M.B.) Examination of the University of London has been won by Mr. Arthur Eastwood, also a student in this department. As the teaching of pharmacology in England compared with that of some of its sister sciences is at a low ebb it is a pleasure to record successes of this kind from so youthful a department as that at Cambridge.

THE TREATMENT OF ELEPHANTIASIS BY ELECTRICITY.

IN *La France Médicale* of June 24th, 1898, Dr. Albert Weil has published a case of elephantiasis in which a remarkable result was obtained by galvanism. An obese washerwoman suffered from extreme elephantiasis of the legs which had developed gradually during twenty-seven years. The circumference of the left leg measured 57 centimetres and of the right leg 55 centimetres and the patient weighed 128 kilogrammes. Bandages were used, but without effect. A constant current to the left leg was then tried. Two metallic electrodes covered with chamois-leather measuring 16 by 26 centimetres bent into half cylinders were applied to the leg so as to cover more than the lower half, and connected with the negative pole of a battery. The positive electrode, which was 10 by 26 centimetres, was placed on the nape of the neck. A current of 20 milliampères was passed for a quarter of an hour and the leg was then compressed with a bandage. The right leg was similarly bandaged. This treatment was repeated at intervals of two or three days with currents ranging up to 50 or 60 milliampères. On the fifth day the left leg measured 54 centimetres, on the twelfth 53 centimetres, on the seventeenth 50 centimetres, and on the thirty-third 45 centimetres, when elastic bandages were substituted for the cotton ones and applied to both legs. In a fortnight the left leg measured 40 centimetres and the right 54 centimetres (a slight diminution). A constant current was then applied to both. After twelve days the measurements were 38 centimetres and 50 centimetres. Finally they were reduced to 38 centimetres and 40 centimetres, and the patient could walk and, except for some slight swelling at the external part of the ankles, was practically cured. Electricity in the treatment of elephantiasis has been recommended by several writers especially and in repeated publications by two Brazilian medical men—Silva da Aranjo and Moncorvo. But its use has not become general. Elastic bandages often give brilliant results. Though Dr. Weil appears to have produced quite cogent evidence of the value of electricity in his case it would have been more satisfactory if he had employed elastic bandages before resorting to that treatment. His explanation of its mode of action is that it facilitates the movement of lymph by exciting contractions of the lymphatic vessels. The interrupted current, which would seem more effectual than the constant for this purpose, is recommended (in addition to the latter) by the Brazilian writers, but for some reasons it was not employed by Dr. Weil.

PLUMBERS IN CONGRESS.

AT Glasgow on Aug. 18th the corporation entertained some 300 members of the Association for the National Registration of Plumbers on the occasion of the ninth annual Scottish Congress. In addition there were present several Members of Parliament, medical officers of health, and representatives of various sanitary and municipal authorities interested in the subject of sanitation. Ex-Bailie Crawford, D.L., President of the Congress, made in his address a startling statement, but one which, it is to be feared, was by no means exaggerated. As an argument in favour of the registration of plumbers he stated that during his chairmanship of the health committee of Glasgow the percentage of cases in which plumbing work when tested was found to be satisfactory was very small. As a matter of fact, from 60 to 70 per cent. of the cases tested were found to be in some way defective, although he did not attribute these defects in all cases to the faulty work of the plumber. He commended the work done by the Association for the National Registration of Plumbers since its foundation in 1884, and thought that the operatives had been stimulated to a higher sense of their responsibilities by the improved opportunities existing for technical education. He deplored that Parliament had not yet been able to give the effect of law to the Plumbers' Registration Bill which had for its object not only the legalisation of the diploma and title, but granted the necessary power for discipline in the cases of those who committed acts unworthy of the craft.

INTESTINAL TUBERCULOSIS.

THE *Journal of the American Medical Association* of June 4th, 1898, contains an important paper on the above subject by Dr. N. Senn, whose name is so well known in connexion with abdominal surgery. The knowledge acquired in the practice of this comparatively recently developed branch of surgery has thrown considerable light on the pathology of abdominal diseases. Intestinal tuberculosis is not often found as a primary disease. In 1000 necropsies on tuberculous subjects at the Munich Pathological Institute only one case was observed, whilst there were 566 secondary cases. Tuberculosis of the stomach usually occurs in connexion with disease of the intestines and lymphatic glands. It is rare; Letorey states in his thesis that he could find only 21 cases. The destructive action of the gastric juice on the bacillus protects the stomach against invasion. Intestinal tuberculosis pursues a more benign and chronic course in adults than in children. The lower portion of the ileum and the ileo-cæcal region are the most frequently affected. A number of cases of hernial tuberculosis have been reported. In 13 cases the sac was attacked 10 times and in 7 it was alone the seat of the disease. Hernial tuberculosis may be primary; generally, however, it is associated with peritonitis. Intestinal tuberculosis may run its course without any symptoms pointing to the alimentary canal. Thus an isolated lesion may cause no symptoms until perforation occurs. Of this a remarkable case is related by Baumgarten. A young soldier in almost perfect health died suddenly from perforative peritonitis. The necropsy revealed a solitary tuberculous ulcer of the size of a penny in

Digitized by Google

the lower ileum and no evidence of tuberculosis in any other organ. Clinically this case is exactly parallel to cases of perforation in ambulatory or latent typhoid fever. In other cases the symptoms are misleading; thus one case assumed all the features of pernicious anæmia. In primary intestinal tuberculosis the symptoms are insidious and are usually mistaken for intestinal catarrh, but the presence of traces of blood in the stools should arouse suspicion. The healing of an ulcer of considerable size is usually announced by symptoms of chronic intestinal obstruction caused by the resulting stenosis. The formation of a chronic abscess in the ileo-cæcal region or in any part of the abdominal wall in connexion with intestinal symptoms of long standing always suggests the probable existence of tuberculous intestinal ulcer.

THE TREATMENT OF INFANTILE OPHTHALMIA.

DR. P. BAR, in a paper quoted by the *Journal de Clinique et de Thérapeutique Infantiles* of August 18th, 1898, discusses briefly the various modes of treatment which have been employed for the prevention of infantile ophthalmia. The writer's experience of iodoform dusted on the conjunctiva has not been more fortunate than that of other surgeons. Neither has he found that the use of boric solution, or even of perchloride of mercury from 1 in 1000 to 1 in 4000, is entirely satisfactory. The only remedy which he considers to be truly reliable is the time-honoured solution of nitrate of silver, and the mode of its employment by him, though not novel, is sufficiently unusual to merit a passing comment. The strength of the solution, 1 per cent., is somewhat weaker than that commonly advised and we are pleased to find that it is administered by instillation. This method, it is stated, has yielded excellent results and the statement, we believe, is justified by the experience of other practitioners besides the writer of the paper above mentioned. It possesses this great advantage over the more common practice of brushing a stronger solution over the conjunctiva—that it avoids an obvious cause of local irritation, and we believe the results obtained by the drop method will be found to be, at all events in cases taken reasonably early, not only more successful but more rapidly attained. Dr. Bar advises the routine use of the nitrate solution as a prophylactic for all newly-born infants. This is certainly suggestive of *nimia diligentia*, but as regards the value of this treatment for infantile ophthalmia in its early stage there can be no question.

THE REPORT UPON IRISH PRISONS.

THE twentieth report of the General Prisons Board for Ireland has just been published. With regard to local prisons, the number of committals for 1897 is 34,911 as against 32,916 for 1896. The number of local prisons has been reduced by one owing to the closing of Grangegorman Female Prison in August, 1897, and the prison has been utilised as a temporary lunatic asylum to relieve the overcrowded condition of the Richmond Lunatic Asylum. As regards juvenile prisoners there has been a slight increase over the numbers for 1896—i.e., 221 as against 207—but a decrease as compared with 1895, when the numbers were 257. During the year there were 81 cases of insanity; of these 59 were insane on admission and 4 were sane while in prison but were found to have been insane when the offences they were convicted of had been committed; only 8 became insane while in confinement. In convict prisons there were in custody on Dec. 31st, 1897, 311. Since the years 1883–1884 the number of convicts has been reduced by one-half. It has, we are glad to see, been arranged that Irish military convicts convicted outside the United Kingdom should serve their sentences in Ireland so that they will not be deprived of the privilege of visits from their relatives and friends. With regard to the employment of prisoners the most satisfactory form seems to be garden work, and this is specially undertaken at Belfast, Maryborough and Tralee. Other employments are washing for certain barracks and the Dublin Police and making mail-bags for the Post Office. The Prisons Board are "glad to be able to state that no unproductive mechanical employments, such as the treadmill or the crank, are in use in Irish prisons." This is a point upon which the Board is much to be congratulated. The various reports of the medical officers of the different prisons show nothing very noteworthy except that the sanitary condition of the prisons seems remarkably good. In both local and convict prisons there were only 9 deaths among prisoners during the year 1897.

THE second meeting of the Congress of Gynæcology, Obstetrics, and Pædiatrics will be held at Marseilles on Oct. 8th, 1898. Medical men who wish to read papers or to bring communications before the Congress are requested to send in their names with the subjects of their communications to the general secretary, Dr. Queirel, 20, Rue Grignan, Marseilles.

ON Saturday last, August 20th, Princess Henry of Battenberg, the President of the Victoria Society for Nursing the Sick Poor, attended a meeting at Gosport in support of the society, which was founded as a memorial of the Queen's Diamond Jubilee.

THE REPORT FOR 1897 OF HER MAJESTY'S CHIEF INSPECTOR OF FACTORIES.

THIS report, the receipt of which we acknowledged last week, is one of the most important publications which have issued from the Home Office for a considerable period. At the present time more than ordinary interest attaches to the chief questions dealt with in this report because of the radical and far-reaching changes in the conditions of factory labour which have been brought about by the exceptional and to some extent experimental legislation of the last few years. The Factory and Workshops Act of 1895 and perhaps in a greater degree the Workmen's Compensation Act of last year may be said to have revolutionised the relations of employers and employed in factories and workshops, and it is unquestionably true that many well-informed and experienced employers of labour in this country who are by no means indifferent to the health and safety of their employés are of opinion that unless the utmost vigilance be exercised the tendency of recent legislation, especially of that conceived on the lines of the statute last mentioned, will be to gradually but surely alienate from the factory and workshop interest a great part of the capital which is essential to success and thus in the long run to deprive, *pro tanto*, the industrial classes themselves of the very means of subsistence. The present report is from the pen of Dr. Arthur Whitelegge, who for many years before his promotion to the Chief Inspectorship of Factories was well known as an accomplished sanitarian. His long and exemplary administration of the vast area of the Yorkshire West Riding doubtless marked him out as being pre-eminently fitted to direct the factory system of the country from the point of view of the sanitary reformer. But even a superficial reading of this elaborate and careful report will suffice to show that whilst the real hygienic requirements of the factory and workshop will, under Dr. Whitelegge's guidance, be adequately and judiciously provided for, at the same time the interests of the employers of labour will not be allowed to suffer from the imposition of untried and costly experiments, although these may be clamoured for by ignorant faddists who assume to represent the interests of the workpeople.

Some idea of the amount of work done by the Factory Department may be gathered from the fact that no fewer than 200,000 factories and workshops came under inspection

Digitized by Google

during a single year. Among the operatives in these establishments—four and a half millions in number—there occurred in the year 1897 as many as 40,000 accidents and 1200 cases of poisoning by lead. In the report under notice particulars are given of the nature of the accidents occurring and of the trade processes in which accidents are most frequent. A large proportion of the injuries, however, appear to be of but trifling severity and many of them are shown on inquiry to be exclusively due to carelessness on the part of the workers themselves. For example, we notice the case of a boy who was badly burnt by gunpowder in a factory, not while at work, but during the dinner hour when he was celebrating the 5th of November. Another case was that of a man who was severely bitten by a horse whilst working in a dock; and a third that of a dock-labourer who was injured by the overturning of a hansom cab. A very large proportion of the accidents recorded appear to be caused by the stupid practice of cleaning machinery whilst still in motion, and this notwithstanding the prohibition of the practice by authority. For instance, a boy is reported to have lost part of his hand by being caught in the gearing of a shoe-making machine. He began to clean the machine before it had come to a standstill because he wished to gain time to try a bicycle. Another boy had his hand severely lacerated whilst cleaning a leather-cutting machine in motion; this boy wished to get his cleaning done in order to attend a football match. It is obvious that no precautions by the proprietors can avail against foolhardiness such as this. In consequence of the representations of the inspectors the exposed and dangerous portions of machinery in factories are now being more and more effectually fenced. This has doubtless been brought about by the heavy responsibility incurred by owners under the Workmen's Compensation Act. In one case, where the instructions of the inspector to provide suitable fencing for a lathe had been disregarded and a boy had been badly lacerated in consequence the owner was fined £10, and that sum was, by order of the Secretary of State, paid over to the injured lad. According to the evidence of one of Her Majesty's inspectors, Mr. Tinker, it is probable that the Act first mentioned will indirectly cause a material reduction in the number of preventible accidents, since the use of precautions such as the fencing and guarding of dangerous machinery will ultimately affect the rates of accident insurance. Dr. Whitelegge remarks, on the strength of evidence supplied by various medical officers of health, that increased attention is now being paid by local authorities to the sanitary condition of factories and workshops. He quotes as specially worthy of imitation the action of a large manufacturing firm in Cardiff, who have issued a notice forbidding any of their workpeople in whose house a case of infectious disease exists to return to work until the medical officer of health permits them so to do. The firm urge upon their employés the advisability of promptly sending infected members of their families to the borough sanatorium, and if they comply with this advice the firm undertake to pay the wages of any employé who is kept away from work pending the disinfection of his house. Dr. Whitelegge gives important information which we can only notice briefly regarding the prevalence of lead, phosphorus, and arsenic poisoning and of anthrax in factories and workshops. The figures under this head compare unfavourably with those of 1896 and there is reason to fear that the numbers would be still larger if all the cases were known. Steps are being taken, by advertisement and otherwise, to call the attention of medical men throughout the country to their statutory duty of notifying all cases of this kind which occur in factories and workshops. At page 49 a list is given of the trade processes in which poisoning by lead, phosphorus, or arsenic is most likely to occur; from the two latter the cases of poisoning reported are but few in number at present. There was a great increase in the reported cases of lead-poisoning in 1897 as compared with the previous year, the increase being common to all the industries included in the list. Speaking of the dangers (including lead poisoning) incidental to the potter's or earthenware manufacturer's occupation Dr. Whitelegge says that during the last few years there has been a material improvement in "dust conditions" which may be expected to produce an effect upon the records of fatal phthisis and other diseases of the lungs. But of lead-poisoning, unfortunately, the same cannot be said, the number of grave cases reported, and particularly of cases of blindness, having ominously increased of late. Full investigation of the subject is now being made, with a view to better measures of prevention, and in this the Secretary of State has secured the assistance of Dr. Thorpe, F.R.S., the principal of the Government Laboratory, and of Dr. Thomas Oliver.

The reported cases of anthrax increased from 17 in 1896 to 23 in 1897. 14 of these were connected with the handling of hides and skins and 9 with wool-sorting. The former industry has now been certified as a dangerous trade by the Secretary of State. Special rules for wool-sorting have been served upon the occupiers of all works in which the sorting of the dangerous kinds of wool and hair is carried on.

A special feature of the present report is the prominence which is given to the work of Her Majesty's lady inspectors of factories, whose reports to the Chief Inspector are in many cases of unquestionable merit; they occupy a considerable portion of the volume. There seems to be great difficulty in controlling the employment of women in factories within a limited period after childbirth. There is considerable danger, according to the inspectors, that the section of the Act of 1891 dealing with this question, which is of such great importance to the rising generation of workpeople, will remain a dead letter because of the difficulty of proving the employer's knowledge of all the circumstances. It is suggested that the production of a medical certificate of fitness for employment in a factory should be made a condition of employment or of re-employment of any woman after confinement. An illustration is given in the report of the need of protecting witnesses from the intimidation, direct or indirect, of those who employ them. Hardly any infringement of the Factory Acts is more difficult to discover or proceed against than the employment of a woman within four weeks of her confinement, chiefly owing to the burden of proof resting with the inspector as to the employer's knowledge of the facts. In one case, the particulars of which are given in full, an unfortunate woman who had been employed within the prescribed period of her confinement was dismissed from her employment because she was called as a witness in her own case by Her Majesty's inspector. Happily, the poor woman obtained re-employment from one of the magistrates who heard the case and so her personal difficulties were surmounted for the time. This would do little or nothing, however, to counteract the effect on the worker's mind of the conduct of the employer, who by dismissing her showed his contempt for the law and indicated plainly the course he was likely to pursue in future with respect to any worker who admitted facts as to infringements of the statute to one of Her Majesty's inspectors. The new Truck Act of 1896 has added much to the work of the factory inspectors, bearing as it does upon all factories and workshops and upon all employers in the United Kingdom, and raising many complex questions which the inspectors are called upon to decide. In order to make clear to both masters and men the requirements of the Truck Acts, which were at first misunderstood, explanatory memoranda have been prepared and issued by the Home Office with good effect. Several flagrant cases of violation of the Truck Acts are mentioned in the report, in most of which convictions were obtained. In one case, a tailor, who was forcing his workers to spend nearly all their earnings in his own grocery store, was fined £10 and costs. In a second, a large bootmaker was charging his workmen an exorbitant price for materials and compelling them to buy more than they needed; he was fined £5 and costs. In another case, a grocer, acting as agent for a glove manufacturer, gave out gloves to be sewn and paid for the work in groceries, which the people had sometimes to sell again in order to obtain money for other necessaries. Armed with powers under the new Act the inspectors have been able to put a stop to many of these cruel extortions, which have now become for the first time apparent under the compulsory publicity which the Act demands.

TYPHOID FEVER IN BELFAST.

AT a meeting of the Public Health Committee of the Corporation of Belfast held on August 18th a very serious state of affairs was reported by the medical officer of health in reference to the prevalence of typhoid fever, for during the week ending August 13th 198 cases of zymotic disease were notified, and of these 143 were typhoid fever. The only

Digitized by Google

comforting piece of intelligence in this most serious aspect of affairs is that the number of cases of infectious disease is 52 less than in the preceding week. There are over 200 cases of typhoid fever in the Union Fever Hospital and several members of the Fire Brigade have been attacked, due, it is said, in their case to eating cockles purchased from a hawker who had obtained them from the shores of Belfast Lough, which are polluted with sewage matter. It is a most noteworthy but sadly deplorable fact that a new city like Belfast is a hotbed of typhoid fever, the most preventable of the zymotic diseases, and the citizens must have read with sincere chagrin the fact noted in Sir Charles Cameron's presidential address at the Congress on Public Health in Dublin that while the mortality caused by typhoid fever is greater in Dublin than in nearly every other town in the United Kingdom, in Ireland Belfast alone has a higher death-rate from this disease. Belfast has now a new corporation, the great majority of the members of which when candidates for municipal honours placed the sanitation plank in a prominent position in their election platform; but so far nothing has been done to grapple in the least degree with the causes of the wide prevalence of a disease which every student of medicine is taught should be preventable. Before matters can be put right the causes of the prevalence of typhoid fever in Belfast must be known, and they may be placed under the following heads: 1. The long-continued pollution of the soil which the authorities allowed in spite of constant warning by permitting up to quite recently all over Belfast notices—"Rubbish may be shot here." Houses have been erected on such "made soils" without the least attempt to disinfect the material of the foundations. Hence, like Dublin, the soil of Belfast is full of the germs of typhoid fever. 2. Defective house drains, allowing pollution of soil by escape of sewage matter. It is found that this mischief generally occurs in the drains (in the yard) between the houses and the main city sewers. These pipes are sometimes only cemented on the top and sides, the lower part resting on the ground being untouched and so allowing leakage. Again, it has in Belfast unfortunately been a custom to allow the joints of these pipes to be made often with clay, which after a time washes out and so sewage escapes. The clay is used because it is cheap, a good example of the "penny-wise and pound-foolish" principle. Then too often in the "jerry" houses drain-joints are made, not as they should be by skilled men, but by those who are called "handy" men or labourers. A leading citizen of Belfast, in a letter to one of the daily newspapers of that city, says as a result of his most unfortunate experience with several houses in Belfast (and he relates a number of examples): "I would not allow any drain-pipes to be covered in without being tested by smoke and water in my own presence." 3. It often happens that in the poorer districts if there is a case of typhoid fever in a house all the dejecta are thrown into the ashpit, which is generally open and near bedroom windows. In this way the poison is wafted about and other persons become affected. It is said there are 20,000 houses of this type in Belfast, and as many of them have no back passages the horrible nuisance of the contents of such ashpits being carried through the house and out at the front-door (this being the only passage) can easily be imagined. 4. If the street gullies are to be effective the traps must be kept full of water. This during the present hot weather is not done and hence the water evaporates and the traps become open ventilators from the sewers. Anyone walking through Belfast must have in the present weather perceived horrible odours constantly emanating from the sewers through these dry traps. 5. As a result of the present main-drainage system of Belfast the whole of the sewage is emptied a short distance down the Lough, and, owing to the tidal currents, a great deal of it is spread over the sloblands on both sides of the Lough. During the present summer, to railway travellers on either side of the Lough the stench at many places is simply horrible, and as northerly winds have been blowing very often of late from these perfect culture grounds (pathologically speaking) towards the city germs of disease may in this way be carried to the inhabitants.

A few of the causes of the prevalence of typhoid fever in Belfast have been mentioned. Every thoughtful citizen is asking what is to be done. Some are crying out (and rightly so) against jerry-building and jerry-plumbing, but if the medical profession were to be asked their opinion they would say at once: remodel the whole public health department of the city and appoint a really sufficient staff, as it is at present altogether under-manned. Let the heads of that department tell the corporation plainly that the present cheap way of carrying on the health department must cease and that as much money must be spent in the care of the health of the citizens of Belfast as is done in other places. Let them point out clearly and fully what is done in Glasgow, in Birmingham, and in Edinburgh, and we are fully confident that the citizens of Belfast will support them and that the scandalous state of affairs at present existing (we mean the fact that a new city such as Belfast has a death-rate from a preventable disease like typhoid fever the largest in the United Kingdom) will cease for ever. Belfast has one of the finest tram systems in the world; it has (and all thanks to the corporation) one of the finest fire brigade systems in the world; why, then, does it lag behind all other cities in its care of the public health? These remarks are no whit too strong for the state of matters, and the results are well seen in a telegram from our Belfast correspondent dated August 24th. He says: "100 new cases of typhoid fever were admitted last week into the Union Fever Hospital and the total number of typhoid fever cases there is 307. No more cases can be admitted before additional accommodation is provided, and the board of guardians has decided to employ additional medical men and nurses. At a special meeting of the Public Health Committee held on August 23rd it was decided that Dr. Lorrain Smith should conduct a bacteriological investigation into the causes of the epidemic. The citizens were advised to boil all water and milk."

THE HOSPITAL REFORM ASSOCIATION AT EDINBURGH.

IN THE LANCET of July 30th we gave a short *résumé* of the proceedings at the meeting of the Hospital Reform Association which was held at Edinburgh on the morning of July 26th. We now supply our readers with an abstract of the various papers read and some figures concerning hospitals and dispensaries in Scotland.

Mr. GARRETT HORDER (the President), in his opening address, after a few introductory remarks, said: To those who are anxious to make themselves acquainted with what has been done for reform in the past I would refer them to the report of the proceedings of the Ethical Section which met for the first and apparently for the last time in the border city of Carlisle. As far as I can learn there has been no attempt at any time to deal with the Hospital Reform question in any of the Scotch towns. In Glasgow there are several medical men who have written on the subject, but beyond a series of articles in THE LANCET I have not heard of any systematic attempt to bring about a more desirable condition of things. You will have noticed that we are desirous of effecting three objects—viz., (1) the prevention of abuse of hospitals and dispensaries; (2) the formation of central hospital boards; and (3) the promotion of provident dispensaries. That medical charities are abused, and abused to a large extent, no one who has looked into the question can have any doubt whatever. From an educational point of view (and this is naturally of the highest importance in such a city as Edinburgh) the massing together of such large numbers of patients is not likely to lead to the advancement of medical knowledge. The medical officers have not the proper amount of time to teach the students and the students themselves become too wearied to derive much benefit from the clinical remarks of the medical officers. For educational purposes it is distinctly beneficial to limit the number of out-patients to be seen by each medical officer. Moreover, the herding together of large masses of peoples in rooms for many hours at a stretch must be condemned not only from a medical but from a sanitary point of view. Neither is this indiscriminate system fair either to the hospital subscribers or to the medical profession. Looking at the subject from an ethical point of view I would ask those who have had experience in dealing with the poor whether this indiscriminate medical relief is not likely to produce a loss of independence amongst the working classes and ultimately to tend towards pauperising them. It is perfectly evident that the managers of hospitals are too fond of boasting of the large number of people who patronise their institutions and I imagine that this is done mainly because of the difficulty experienced in

Digitized by Google

raising sufficient money to support their establishments. Surely the time has arrived when the managers in our big towns should meet together and see whether some measures cannot be adopted to bring about a common understanding. In your large cities there would, I imagine, be little difficulty in effecting a closer relationship between all the medical charities than now exists; in a word, forming central hospital boards. May I be allowed to congratulate you that in this city and also in the city of Glasgow you have as managers of your Royal Infirmaries men representing in an official capacity the learned professions, the commerce, and the town authorities? With such able representatives it would be comparatively an easy matter to bring about a conference at which the whole subject could be threshed out to the satisfaction not only of the hospitals but of the sick and suffering poor. You may well ask what our ideal out-patient department is; it is briefly this, a place where persons who have been in-patients and who still require further treatment can obtain it, and also a place where general practitioners could either bring or send patients suffering from obscure or difficult diseases for the purposes of consultation. We feel that there should be a much closer intimacy between the hospital staff and the general practitioners than now exists. And now to come to the question of your system in Scotland. I have prepared a table showing the hospitals and dispensaries in the 8 principal towns, together with the number of in- and out- (or dispensary) patients attending during the year 1897. As these figures have been chiefly compiled from the reports you may I think, consider them as approximately correct. In several instances the figures refer to the year 1896, because the reports of last year had not reached me. I want you to clearly understand that the numbers referring to the out or dispensary patients are actually the number of patients and not the number of attendances made by them. [The tables showed the following results: Glasgow with 18 institutions giving medical relief, exclusive of the Barony (Parish) Hospital and the City Fever Hospital, has in-patients, 20,863, and out-patients, 78,302. Edinburgh with 23 institutions, 2 of which sent in no returns, has in-patients, 14,763; and out-patients, 109,141. Leith with 1 institution has in-patients, 1152; and out-patients, 18,312. Dundee with 3 institutions, 1 sending no return, has in-patients, 2687; and out-patients, 18,516. Aberdeen with 6 institutions has, in-patients, 3006; and out-patients, 19,384. Paisley with 2 institutions has, in-patients, 1086; and out-patients, 10,258. Greenock, 2 institutions, in-patients 1455; out-patients, 12,217. Perth, 1 institution, in-patients, 1163; out-patients, 1236. Mr. Garrett Horder continued:] I know that some patients come to your hospitals from places outside. But even allowing a deduction of 20 per cent. for such patients you will see that the figures remain very large indeed. And in passing I should like to make a remark about patients coming from a distance. It is flattering, no doubt, to the managers and to the medical staff to find their institutions patronised by strangers to the district, but is it quite fair to the subscribers to be called upon to pay for the treatment of people who reside in places so far distant from Edinburgh as Carlisle, South Shields, Sunderland, London, Newcastle, Birmingham, Middlesborough, Liverpool, Sheffield, and Leeds? One would naturally have thought that there are hospitals in those towns where diseases could be treated quite as effectually as they could in the Royal Infirmary of Edinburgh. This is an important point, as I notice during last year no fewer than 295 of the in-patients belonged to places outside Scotland. With regard to the administration of your hospitals as compared with those of England the chief points of difference seem to me to be as follows: in Scotland the out-patients are called dispensary patients and with few exceptions receive medicines and advice as they do in England. In the Edinburgh Royal Infirmary, in the Chalmers Hospital, and in the Ayr County Hospital only advice is supplied to such patients. I notice also that in many of your dispensaries a large number of vaccinations are performed. Apparently this seems an injustice to the general practitioners and to the Poor-law medical officers. I say apparently, because I am not sure whether any fees are received for such vaccinations. Touching on the question of provident dispensaries I can only find evidence of the existence of one in the whole of Scotland—the Edinburgh Provident Dispensary. It is gratifying to note that that one is very successful, having a membership of over 8000. There is just one point about that institution which is worth recording and that is that it has medical officers for the treatment of special diseases. I have given some attention to the subject of provident dispensaries lately and I have come to the conclusion that if we are desirous of seeing a greater number established we shall have to take steps to see them more fully equipped than they are at present. It is generally acknowledged that the special hospitals and the special departments of general hospitals are more abused than any other; and I think much could be done to lessen that abuse by attaching to provident dispensaries a certain number of specialists so that people would have no reasonable excuse for seeking gratuitous aid when they were in a position to pay something for it. I have occupied so much of your time that I cannot afford to dwell on the subject of provident dispensaries generally. I will content myself by saying that if the following regulations are adopted by the managers it is probable that the institutions would be more cordially supported by the profession at large than they are at present: (1) the adoption of a wage-limit and effective means to see that that wage-limit is adhered to; (2) the representation of the medical officers on the committee of management; (3) the prohibition of all canvassing for members; (4) the periodical revision of the list of members; (5) the placing of all medical men who wish it on the medical staff; and (6) the more economical administration: that is, with respect to establishment charges, official salaries, &c.

The Medical Control of Medical Charities.

Dr. DAVID WALSH read a paper under the above title After stating that various inquiries had been made into the question of the abuse of medical charities which had proved that such abuse does exist, to the detriment of medical men, he continued: The truth or otherwise of the allegation, however, does not materially affect the main proposition here advanced—namely, that medical men are entitled to a voice in the management of medical charities. In spite of the above-mentioned consensus of opinion nothing has been done, except in a few trifling instances, to abate the evil. The need of action has long been admitted on all hands; the question is how to bring the requisite leverage to bear upon the charities. What are the facts of the case as regards the executive management of the charities? In most cases they are under the control of laymen, who may or may not appoint a small proportion of the medical staff as *ex-officio* members of the governing committee—that is to say, the medical element, small as it is, does not represent the main mass of the profession, but individuals who, however honourable and distinguished, belong to a body whose interests are those of a section untouched by hospital competition. So that, as a matter of impartial statement, the charity that depends on the gratuitous services of the medical profession for its existence is managed by a body of persons who are out of touch with the wants, wishes, interests, and aspirations of the profession chiefly and vitally involved. The public is doubtless in sympathy with medical men and so are the lay committees, but they fail to realise the strictly utilitarian conditions under which the profession has to be followed. Humanitarianism is not allowed to interfere with the internal usages of other professions. For instance, imagine for a moment a charitable body for dispensing gratuitous law to needy folk and having organised such a body to demand that its executive should contain no lawyers. The absurdity and injustice of such an arrangement would be self-apparent, yet the cases of law and medicine, which are both necessities of civilised life, are to a great extent analogous and comparable. Obviously one remedy is to have on the executive of our medical charities medical men who can insist upon a fair and proper treatment of the general practitioner. By a well-considered scheme for securing such representation throughout the country it is likely that more practical good would be effected than by a generation of discontented and abstract discussion. If there be justice in the cry against the abuses of the out-patient departments of the hospitals what reasonable objection could be raised against the representation on the executive of the persons most closely affected by such abuses? The good that could be effected by such an arrangement has recently been fully illustrated in a hospital at Tottenham, where certain practices had crept in of a nature injurious and objectionable to the medical men of the district. However, on the executive there were fortunately two medical men who held permanent and *ex-officio* posts on the committee. In the end they compelled the management to arrange the conduct of

Digitized by Google

the hospital in a way satisfactory to the medical men of the neighbourhood. If every medical charity in the country had its contingent of general practitioners on the management it seems likely that many of the difficulties which now surround the situation would be speedily settled, or indeed would never have arisen. The professional philanthropist who has hitherto held the reins has not made a distinguished success of hospital management in its relations to the main body of the medical profession. The question naturally arises whether medical men would not themselves be competent to manage the charities that depend upon their gratuitous professional services for their existence. At any rate, the proposition is one which may be discussed with advantage in a meeting of this kind.

Provident Dispensaries.

Dr. OTTO WUNDERLICH presented a report to the association on Provident Dispensaries. He said: Among the remedies for preventing hospital abuse the extension of the provident dispensary system is regarded with favour by many would-be reformers. Two questions arise: (1) do provident dispensaries prevent hospital abuse? and (2) is the remedy in itself an entirely satisfactory one? After pointing out that provident dispensaries were quite as much in need of reform as hospitals he continued: The fees which are paid to the medical officers of provident institutions are smaller even than the average fees paid by friendly societies. It does not necessarily follow that they ought to be raised, because it might be objected that a medical man gets his *quid pro quo* by the introduction the work gives him to other patients. This argument, however, is quite fallacious. There are many districts where everybody belongs, or might belong, to a provident institution. In such a district the criterion by which to fix the minimum subscription is the ability of a medical man to earn a living on provident subscriptions alone. We find that with this mode of reckoning even the fees of friendly societies work out unsatisfactorily. With an annual subscription of 4*s.* per patient a medical man attending his full complement of 2000 patients could only earn £400 per annum. It is scarcely necessary to point out that with this amount he could not make both ends meet. If it were only the pauper class who availed themselves of the privilege of paying these small subscriptions nobody would raise any objection. The very poor are those for whom hospital out-patient departments were designed and anything which will lighten the work by their voluntary efforts is altogether admirable. But those persons who are generally recognised to make an unjustifiable use of free hospital treatment are also those persons for whom the present rate of provident subscriptions is totally inadequate. If this is admitted it will follow that to endeavour to replace the hospital out-patient departments by a system of provident dispensaries as conducted under actual conditions will amount merely to replacing one form of abuse by another. The remedy which is usually suggested for these abuses is a wage limit. In the same manner as the medical tariff varies with the value of a patient's house, so the rate of provident subscriptions ought to vary with the wages earned. The moment the limit at which real poverty ceases is reached hospital abuse begins and the present rate of provident subscriptions becomes inadequate. The rate of 4*s.* a year is fair only for the pauper class and persons earning less than 20*s.* or 25*s.* a week. A rate of from 6*s.* to 8*s.* a year might be held sufficient for persons earning up to 30*s.* and 40*s.* a week, whilst a rate of 10*s.* a year would suffice for any person whosoever who did not mind putting up with the restrictions and inconveniences attendant upon provident work. How far such a scheme is from being realised in provident institutions is well known. Their great defect is a lack of elasticity; their fees are not adapted to the means of the members, but are only framed to meet the requirements of the very poor. The following points merit the attention of the Hospital Reform Association. The competition between free hospital out-patient departments and provident dispensaries tends to depress the rate of subscriptions. Only if free out-patient departments are abolished will it be possible to put them on a proper basis. Like most charities provident dispensaries bid for patients to swell the returns and for that purpose they reduce the scale of subscriptions. This would be impossible in the face of opposition from the medical profession except for the reason that they maintain an injurious control over their medical staffs by limiting their numbers. They compel them to work at impossible figures through fear of incurring a serious loss if they should resist. Any discrimination between medical men in a district leads to the formation of fresh dispensaries by those medical men whose services are not admitted. This competition between dispensaries is another cause for an undue reduction of the subscriptions. Dispensaries become regular "corners" in providence. All these considerations affect two points mainly—the subscriptions and the medical staffs—and the following recommendations in regard to them are herewith submitted to the Hospital Reform Association for their adoption. 1. Subscriptions: The provident subscriptions should vary with the income or wages of the members. In practice, and in order to realise a scale which would also take into consideration the ages and infirmities of the members, it is recommended that every medical officer should make his own terms with each of his patients. Although this has not been generally done the system is perfectly feasible. The ordinary competition among members of the staff would be sufficient to prevent any abuse. 2. Medical Staffs: Medical men should be adequately represented on the management committees. They should be irremoveable except with the consent of the majority of their colleagues. Every medical practitioner residing in the district, except such as are debarred for ethical reasons, should be at liberty to join in the work.

The Defence of the Profession against Provident Dispensaries.

Dr. W. RICHARDSON RICE, honorary secretary of the Coventry Public Service, read a paper under the above heading. He said: The profession has now for many years been in a state of agitation over the question of provident dispensaries and it is evident that the time is now ripe for some definite action to be taken in this matter. It is of such vital concern to many of us as medical practitioners to have this question settled on a rational basis that I venture to suggest some means by which a definite result may be attained. It may be taken for granted, I suppose, that the agitation in connexion with the provident dispensary at Coventry is well known to all readers of THE LANCET and the *British Medical Journal*. Since the year 1893 we have been directing a determined attack on this institution. It may serve as an object lesson in medical politics and the lessons to be derived from this conflict may throw some light on the best methods of attack. In the first place we may assume that it is useless to appeal to any sense of fairness in the minds of those who are mainly responsible for the evils incidental to the management of these concerns. To the observant critic one point is clearly demonstrated in these cases and it is this, that the so-called modern working man, though ardently attached to the principles of his trade union, bitterly resents any attempt at combination on the part of medical men. The most striking phase in this movement indicates that those most in evidence are men in easy positions, such as foremen in factories, small manufacturers and the higher type of artisan, men of push and intelligence, who appear to have more object in promoting their own interests than the welfare of their humbler workers. If the so-called working man is met on a committee he is always to the front, abundant in talk, fertile in suggestion. His object always seems to be to assert his own individuality rather than promote the good of the cause he is supposed to represent. What follows as a natural consequence of this spirit? It is simply this, that in institutions managed by this class of man the benefits go to those who assert their own position and the poor and destitute are crowded out. If any radical change is possible in this matter it must be started from within our own ranks. If it needs must be that offences come let us attack and ostracise those through whom they come. Having assumed this much, let us see what steps can be taken against those who hold office in these dispensaries. In the Ethical Section of the British Medical Association we have met, deliberated and passed resolutions concerning the abuses of hospitals and dispensaries. In due course they have been sent to the council. In all seriousness may I ask what has been done or appears likely to be done? These gentlemen sit in solemn conclave and deliberate in stately dignity on these matters. They deliver the usual official reply couched in diplomatic terms and there is an end of it. Gentlemen, the only remedy we have in the matter is agitation, constitutional agitation if you like, but agitation loud and strong. Let me give you in detail some of the steps we have taken in Coventry with the present results. We have reported the case of two practitioners to the Royal University

Digitized by Google

of Ireland and the College of Surgeons of England. We have received no encouragement from them. Apparently they have no power at present or desire to inquire into the conduct of their graduates or licentiates. We are also attempting through the agency of the Association to attack the medical staff at the dispensary. They have made desperate efforts to defend their position as they dislike to confront the professional odium which this situation throws upon them. We have succeeded after much effort and persistent agitation in getting the institution condemned by all the leading organs of medical opinion. [Dr. Rice here quoted from the report of the Special Commissioner of THE LANCET, the *British Medical Journal*, and the *Medical Times and Hospital Gazette*. He continued:] We laid an indictment last year against the medical staff before the Ethical Committee of the Association. They referred the case to the Ethical Committee of the Birmingham and Midland Counties Branch, who reported to this effect: (1) that the dispensary medical staff hold appointments in an institution which has been condemned by the *British Medical Journal*; (2) the low scale of remuneration they accept seriously interferes with all medical fees in the town; (3) there is no proper attempt at enforcing what is known as a wage limit and the Public Medical Service has been established expressly to uphold the principle; (4) that the staff are in the hands of a lay committee; (5) that the dispensary touts for members; and (6) that they exploit the medical profession for pecuniary gain, as surplus funds are not all divided up among the profession. This report was published in February, 1897. The controversy has been going on with the Council of the British Medical Association since this time and it is our fervent hope that the members of the Association at this present annual meeting at Edinburgh will force the Council to make some definite pronouncement and if necessary declare that the position of this medical staff is not consistent with the dignity of the membership of the Association. This matter is more than of local importance to us at Coventry and may form a valuable precedent to guide future measures of reform. Pressure must be brought to bear on the Council so that stringent measures be adopted towards those members who defy, not only the opinion of the *Journal*, but also that of the Ethical Committee of the branch in which this work is carried on. It may be argued that men who are not amenable to the opinion of their professional brethren will care but little for expulsion from the Association. Possibly, however, the stigma rising from such an unenviable position would act as a powerful lever in some cases at least, causing these men to seriously reconsider the position in which they might be placed, and we could fain believe that some might be influenced by a strong condemnation from the representative Council of their profession. In addition to these measures of attack we must not neglect the effort at some means of constructive reform. In course of time we may thus be able seriously to undermine the strength and influence of these dispensaries. Medical men, as a rule, are not remarkable for their aptitude in transacting business; their early training and generous instinct unfit them for such work. In their efforts, however, to further the progress of their art they must take note of their opponents ever eager to pursue a commercial line of policy and organise their forces against the dismembered masses of an overcrowded profession. We must try to exterminate the middleman who comes between us and our patients. In the year 1893 we started in Coventry an organisation under medical control. We called it the Public Medical Service and established it on an ethical basis. This must be regarded as an essential feature in such movements, as it gives control over the conduct of its members and prevents the possibility of any practice infamous in a professional respect. We have at the present time a staff of 13 medical men. A few are not engaged in the active work but lend to it the support of their approval and sanction. Its chief object is to provide, for small weekly payments, medical relief to those whose weekly earnings are under 30*s*. The exigencies of professional life in Coventry rendered it inevitable that some movement of this nature should be started and it was resolved to inaugurate this service with a two-fold object; in the first place, to break down a most irksome monopoly, and in the second place to endeavour to carry out certain measures of reform. Its success, financially, numerically, and politically, has more than justified the anticipations then formed. An attempt was made to induce the dispensary medical men to coöperate with the rest of the profession in this movement but without success. We have now been able to enrol on our books at the end of our fourth year some 7500 members. The gross collections for last year amounted to about £1500, £916 of which was paid to the medical officers, £343 was paid to the chemists for drugs and prescribing, and £197 was paid to the collectors. It is claimed for the service that having a staff of 13 medical officers who see patients at their own houses at specified times the danger of large numbers collecting in one place is greatly obviated and greater individual attention can be given to each member, a higher tone of professional life is engendered, and greater opportunity given for the scientific treatment of disease. We continue to develop and reform the working of the scheme and are careful to limit the numbers under each medical man so that the charge cannot be brought against us of grinding out advice and medicine in wholesale quantities. The payment of a collector by commission on the number of entries must always form an objectionable feature in these schemes. There is an inducement to canvass which it is impossible absolutely to prevent, but we do our best to prevent it, and we have not been able to devise a different method of collection. In the event of any member selling his practice his vested interest is transferable to his successor and we find by experience that this works out well as we do not allow the patients to change their medical men except at the end of a quarter. Such is the skeleton of our scheme of attack on dispensaries managed by lay committees. If the medical men in every town will only band themselves together in some agency for the supply of medical relief to the working classes they will be taking the most important step in breaking the power of these irregular institutions. In course of time they must weaken their power by drawing from their numbers. If men will not act honourably towards their colleagues we must endeavour to compel them to do so with the help of our great Association, the licensing bodies, and, if possible, through the General Medical Council.

THE CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

THE Congress of the Royal Institute of Public Health was opened in Trinity College, Dublin, by Sir Charles Cameron on Thursday, August 18th, and in spite of the gloom of the weather the scene presented was a brilliant one. The Lord Mayor of Dublin drove in civic state to the Examination Hall, where he received the various delegates, after which Sir CHARLES CAMERON delivered the presidential address, which will be found on page 529 of our present issue.

The actual business of the Congress commenced on Friday, August 19th. At the conference of medical officers of health, over which Mr. T. J. Stafford, medical commissioner of the Local Government Board of Ireland, presided, an interesting debate on the Prevention of Tuberculosis took place. Mr. J. KNOX DENHAM, who introduced the discussion, said he hoped the conference would not close without a strong expression of opinion as to the imperative necessity of every sanitary authority in Ireland taking immediate steps to limit the depredations of this terrible enemy of nineteenth-century civilisation. In these islands one in eleven deaths were caused by it. If we wished to deal successfully with this scourge there were three points to be specially noted—(1) notification, (2) education, and (3) renovation. It was no uncommon thing for at least 100 patients to be treated in the morning at one of the dispensaries and it might be assumed that 20 per cent. of these were tuberculous. The waiting-rooms for out-patients at many of our hospitals and dispensaries left much to be desired, and it would be apparent that the crowding together of so many persons for any length of time might be a fruitful source for the dissemination of the tubercle bacillus. To meet this in a measure he advocated the establishment of a large central dispensary for the treatment of tuberculous diseases. The waiting-rooms would be large, well ventilated, and capable of complete daily disinfection and the consulting-rooms replete with all the appliances necessary for the study and treatment of such diseases, the staff to consist of a consulting medical board composed of representative members of the profession in Dublin, and the assistant staff of medical men, on whom the burden would fall, must necessarily be

Digitized by Google

numerous—numerous in view of the number to be treated, numerous in order that a not too exacting tax be made on their time, that they would be expected to attend at only regular intervals in order that they might be able to devote the time necessary for adequate examination, advice, and treatment. Such an establishment would meet with much public support and would be a great boon to our myriad suffering brethren. Having by means of notification ascertained when and where cases existed the sanitary authority could insist when necessary upon the complete renovation of the rooms occupied by patients, not neglecting whatever sanitary defects might exist in the premises.

Mr. ANTONY ROCHE read a paper on the Housing of the Poor. Papers on the same subject were read in the Parliamentary and Municipal Section. In the latter Section on Monday, August 22nd, Mr. CHARLES PORTER contributed a paper on the Supervision by Sanitary Authorities of Public Water Services in the Hands of Private Companies. The following resolution was passed:—

That this Congress hereby records its warm appreciation of the enlightened efforts of the Right Honourable H. Chaplin, M.P., President of the Local Government Board, to protect the consumers of water supplied by water companies, and ventures to express the earnest hope that during the forthcoming session the Government will introduce a public Bill embodying the proposals submitted by Mr. Chaplin to the House of Commons on June 23rd last.

Professor J. W. MOORE, whose Address will be found on page 534 of THE LANCET, presided over the Section of Chemistry and Meteorology. The programme included papers on Kingstown as a Health Resort; Valentia as a Health Resort; Climatology of Valentia Island; Remarks in connexion with the National Hospital for Consumption for Ireland, with some Meteorological and other Statistics; and Meteorological Tables at Fassaroe.

At the Conference of Army Medical Officers Sir JOSEPH FAYRER, Bart., K.C.S.I., F.R.S., contributed a paper on Enteric Fever among British Soldiers in India. In 1895, he said, there were 71,021 British troops on service in Bengal, Madras, Bombay, and Punjaub respectively, of whom 1870 were admitted to hospital for enteric fever, 477 deaths taking place. Enteric fever was a great scourge of our young soldiers in India, and our army was essentially a young one. The susceptibility of the young soldier under twenty-four years of age was much greater than that of older men, and Sir Joseph Fayrer suggested the expediency of not sending men to India until after this most susceptible period has passed. Major J. BATTERSBY, R.A.M.C., dealt with the Probable Causes of Enteric Fever among our Indian Troops; and Major WESTCOTT, R.A.M.C., contributed some Observations on Etiology, Vaccination, and Serum Diagnosis in Enteric Fever.

In the Section of Preventive Medicine and Vital Statistics papers were contributed on "The Causes and Management of Outbreaks of Typhus Fever Occurring in Rural Sanitary Districts"; "Prevention of Measles in Rural Districts"; "On the Control of Infectious Diseases, with Special Reference to Measles and Whooping-cough"; "The Notification of Measles"; "The Methods and Appliances at our Disposal for the Suppression of Outbreaks of Scarlet Fever, Small-pox, Diphtheria, and Typhus Fever in Urban and Sanitary Districts, having a Population of 5000 and Under"; "Microbial Infection of Milk and other Food Materials"; "The Duties of the Community with regard to Tuberculosis"; "Rabies"; and "The Functions of a Bacteriologist in a Public Health Department." In this Section Sir WILLIAM STOKES on Saturday strongly advocated the treatment of infectious diseases in isolation hospitals. Dr. W. R. SMITH proposed the passing of a resolution condemning the practice of treating infectious cases in general hospitals. This motion, which pointed directly to Dublin, was indignantly objected to by Sir WILLIAM THOMSON, who suggested the substitution of "England and Ireland" for "Dublin." After a breezy discussion the words "in certain localities" were substituted. Among the resolutions passed on Tuesday, August 23rd, when the Congress closed, was one regretting that no steps have been taken in the Local Government (Ireland) Act to render the appointment of county medical officers of health obligatory upon county councils.

The Health Exhibition held in connexion with the Congress was opened in the Royal University Buildings on August 18th by the Lord Lieutenant of Ireland. To adequately describe its contents would be impossible in the space at our disposal, but it may be said to have been almost complete in every detail and should prove a powerful stimulus to the study of all questions relating to public health. As an educational factor the formation of such museums is invaluable.

The banquet was held at the Royal College of Surgeons in Ireland on Saturday evening, when Sir Charles Cameron presided. Among those present were his Excellency the Lord Lieutenant, the Lord Mayor of Dublin, Lord Iveagh, Lord Emly, Professor Smith (President of the Royal Institute of Public Health), the Lord Mayor of Belfast, Sir William Pink, the Right Honourable W. J. Pirrie, Sir George Moyers, Right Rev. Monsignor Molloy, Captain the Honourable C. Cadogan, Sir Henry Thynne, C.B., Sir Henry Cochrane, Dr. Grimshaw, C.B., Captain H. W. Vane, Sir Christopher Nixon, Sir Robert Sexton, the High Sheriff, General Sir Henry Prendergast, Mr. T. W. Russell, M.P., Sir Andrew Reed, K.C.B., Sir Wm. Thompson, Sir Henry Simpson, Mr. James Campbell, Q.C., M.P., Mr. William Field, M.P., Sir William Kaye, C.B., the Mayor of Derry, Mr. A. W. Mason, Sir William Stokes, Mr. T. J. Stafford, Sir George Duffey, P.R.C.P.I., Professor M'Call, Professor Sunderbery, Surgeon-General Preston, the Mayor of Folkestone, the Mayor of Huddersfield, Dr. J. C. Thresh, Baillie Pollard, and Professor McWeeney.

Too much praise cannot be bestowed upon the Executive Committee not only for the way in which they organised the Congress and made rough ways smooth for strangers, but for the delightful series of excursions, &c., which they provided for delegates and members. During the week a luncheon was given by the High Sheriff, Alderman T. D. Pile; a garden party by invitation of their Excellencies the Lord Lieutenant and the Countess Cadogan; a dramatic and musical entertainment by the Corinthian Club; a garden party by Sir Christopher and Lady Nixon; a ball at the Mansion House by the Right Hon. the Lord Mayor of Dublin; and a garden party by the Right Hon. Alderman and Mrs. Meade.

The following honorary Fellowships of the Royal College of Physicians of Ireland and Diplomas in State Medicine of the Royal College of Surgeons in Ireland were conferred on Saturday. Hon. Fellows: Dr. Alexander Crum Brown, F.R.S., Dr. Matthew Hay, and Sir Richard Thorne, K.C.B. Hon. Diploma in State Medicine: Dr. T. W. Grimshaw, C.B. (Registrar-General for Ireland), Sir Henry Littlejohn, Dr. John William Moore, Dr. W. R. Smith, Mr. T. J. Stafford (Commissioner of the Irish Local Government Board), and Dr. J. C. Thresh.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

THE Secretary of State for the Home Department has made the following further appointments of medical referees under the Workmen's Compensation Act, 1897:—

Circuit No. 15 (additional appointment).—Dr. James Ramsay, York.
Circuit No. 24 (additional appointment).—Dr. Thomas Wallace Cardiff.
Circuit No. 28.—Dr. Thomas Dalton, Llandudno.
Circuit No. 30.—Mr. Jabez Thomas and Mr. W. Frederick Brook, Swansea; and Mr. Martin Jones, Aberdare.
Circuit No. 37.—Mr. William Brown Holderness, Windsor; Dr. John Gordon Gordon-Munn, Bushey; Mr. William Lucknow Bradshaw, High Wycombe; Dr. William Collier and Mr. Horatio Percy Symonds, Oxford; and Mr. Robert A. Milligan and Dr. Frank Buszard, Northampton.
Circuit No. 47 (additional appointment).—Dr. Ralph Gooding, Blackheath, S.E.
Circuit No. 48.—Mr. Horatio Nelson Hardy, Dulwich-grove, S.E. Mr. Elliott Daunt, Sevenoaks; Mr. Norman Hay Forbes, Tunbridge Wells; Dr. Charles Pye Oliver, Maidstone; Dr. William Chatterton Bromley, Kent; and Mr. Charles John William Pinching, Gravesend.
Circuit No. 55.—Mr. Charles Henry Watts Parkinson, Wimborne Minster; Mr. William Rendall, Maiden Newton; Mr. Wm. Burrough Cosens, Dorchester; Mr. William George Vawdrey Lush, Weymouth; Dr. F. W. Ramsay, Bournemouth; Mr. H. Coates, Salisbury; and Mr. Edward Charles Garland, Yeovil.

THE LATE MISS FOSTER.—Dr. Slade-King held an inquiry at Morthoe on August 18th upon the death of Miss Winifred Foster. The evidence showed that the deceased was drowned by the ground-swell on August 14th, the body not being recovered until August 17th. Dr. Slade-King said that he had held office in the district for fourteen years and had never held an inquest on a case of drowning. A verdict of "Death by misadventure" was returned. Miss Foster was buried at Morthoe on August 19th.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances of the Bettws-y-Coed Rural District and on Prevalence of Enteric Fever and Diphtheria in the District, by Dr. S. W. WHEATON.[1]—The region of which Dr. Wheaton treats comprises hills, valleys, villages, and hamlets familiar to almost every holiday maker in North Wales. Bettws-y-Coed rural district, some 60,000 acres in area, contains the parishes of Bettws, Capel Curig, Trefriw, Penmachno, and Dolwyddelan. The census population of the district in 1891 was 5598, but in summer time, as Dr. Wheaton points out, the number of inhabitants is probably doubled. In each village and hamlet in the district Dr. Wheaton found a multiplicity of insanitary conditions. Certain of these conditions, such as the absence of public scavenging in the villages, nuisances from defective privies, or from keeping pigs close to dwellings, are common enough in scattered rural communities, and their abundance in the neighbourhood of Bettws can hardly be considered unexpected. But we are scarcely prepared to learn from the report that in this district of mountain streams nearly every village has a water-supply liable to dangerous contamination, or that to judge from the condition of cowsheds and dairies pure milk is as far to seek as pure water. Yet it appears that in the case of Bettws the water-supply of the village is taken from the Llugwy at a point just above the Swallow Falls. Between this point and Capel Curig, three and a half miles higher up the stream, Dr. Wheaton found "abundant evidence of gross pollution of the river by sewage from dwellings"; thus almost all the water-closet and other sewage from Capel Curig passes without treatment to the Llugwy, privies are built over small watercourses falling into the river above the intake, and cottagers living near the stream habitually empty their privy pails into it. Again, in Trefriw village, instead of taking the public supply from the large and unpolluted mountain lake Llyn Crafnant, the water is obtained from the River Crafnant at a point two miles below the lake. In the course of these two miles the pure lake water has received pollution from manured fields and by excrement and refuse from houses near the banks of the river. The public supplies of Cwm Penmachno and of Dolwyddelan are open to similar serious objections. Other defects pointed out by Dr. Wheaton in nearly all the villages in the district are defective sewers and improper means of disposal of sewage, unsatisfactory slaughter-houses, and cowsheds "filthy, overcrowded, and without drainage," in which when the cows are shut up "the crevices are plastered up with filth to keep the air out." Owing to the Infectious Diseases (Notification) Act not having been adopted in the district, information as to cases of infectious sickness was not easy to come by. Dr. Wheaton learned, however, of 13 cases of enteric fever in Bettws-y-Coed last autumn; of other cases of the same disease at Trefriw both in 1896 and 1897; and of 104 cases of diphtheria, 12 of which proved fatal, occurring in the village of Cwm Penmachno since the summer of 1897. As might have been expected from the state of things reported, sanitary administration by the rural district council is practically *nil*. The medical officer of health, Dr. Peter Fraser, has indeed drawn the attention of the district council to many of the sanitary evils of the place, and an inspector of nuisances, whose salary is but £60 for whole-time work, has done his duty in reporting a variety of unwholesome conditions. But the district council has in most cases neglected to apply any remedy, and even when moved to pass resolutions on sanitary matters it has taken no steps to see them carried out. It appears from the report that the Carnarvonshire County Council has now been successfully petitioned to create a separate Bettws-y-Coed urban district. Creation of such small urban districts is in any case doubtful wisdom. In this instance the rural council's neglect of its sanitary duties gives some plausibility to the demand for separation. But it is also a strong reason why that council should be made to do its duty rather than be assisted to shake off its responsibilities.

[1] London: Eyre and Spottiswoode, East Harding-street; Edinburgh: John Menzies and Co.; Dublin: Hodges, Figgis, and Co. Price 2*d*.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hastings Urban District.—Dr. Scarlyn Wilson reports a case of some interest *quâ* the infective power of desquamation in scarlet fever. On examining some school-children he found two members of one family peeling freely from an attack of scarlet fever contracted some six week previously. Apparently these two children had been attending school regularly since their illness, which was presumably not recognised. No other child, however, sickened from the disease in spite of the attendance of these two children until five weeks after the attack, when an outbreak occurred amongst the scholars. The question which occurs to us is whether the outbreak supposed to have been caused by these two desquamatory children was really so caused. Dr. Wilson also furnishes another interesting narrative, this time as to diphtheria. After an outbreak in a boys' school the scholars were sent home, and in eight weeks time, prior to the proposed reassembling of the scholars, a scraping from the throat of each child was examined. In some the bacillus of diphtheria was detected even although these children had never shown signs of diphtheria; nor did they do so subsequently.

Southampton Urban District.—Mr. Wellesley Harris reports an outbreak of pemphigus, apparently what is known as "pemphigus neonatorum." Fourteen infants were affected and the cases arose about the eighth or tenth day after birth. They did not all occur in the practice of one midwife though many of them did so. No satisfactory explanation of the cases was discovered. These bullous eruptions in newly-born infants are very frequently of syphilitic origin, but it is not apparent that this was the cause in the cases here in question. Mr. Harris calls attention to the large quantities of milk which are being imported into Southampton from France. The milk reaches Southampton in large cylinders and is from these despatched in the usual receptacles to its destination. Samples of this milk have been analysed and reported to be genuine milk of average quality; it, however, contains formaldehyde in large quantities. As Mr. Harris remarks, although this milk may in a sense be genuine we have no guarantee as to its being drawn and stored under satisfactory conditions, and it seems rather an absurdity to make stringent regulations as to our home supply and to admit foreign produce without demur—that is to say, unless we can enable the public to recognise what is of foreign origin and what is home produce. In connexion with foreign margarine, too, Mr. Harris has discovered a somewhat amusing, though none the less iniquitous, practice. Margarine from a French factory is taken on arrival at Southampton to a private house where it is worked up into half-pound pats, stamped to resemble butter, and finally hawked around the streets of Southampton by country-looking persons specially selected for this purpose. A question has been raised by Mr. Harris which presses for settlement in places other than Southampton. The fact that the details of house-drainage are so often settled in the surveying or engineering department without reference to the medical officer of health must frequently in such cases lead to friction between the departments and injustice to builders and householders. For the medical officer of health to condemn that which another department has sanctioned and approved is not an easy matter, and yet that is the position in which a conscientious medical officer of health must be frequently placed. Mr. Harris suggests that the building by-laws should provide that no new house shall be occupied until the house-drainage has been certified to be free from defect by the medical officer of health. Clearly some reform is necessary in this direction.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6510 births and 4727 deaths were registered during the week ending August 20th. The annual rate of mortality in these towns, which had increased in the five preceding weeks from 14·7 to 20·5 per 1000, further rose last week to 22·0. In London the rate was 23·4 per 1000, while it averaged 21·0 in the thirty-two provincial towns. The lowest death-rates in these

Digitized by Google

towns were 8·6 in Halifax, 12·4 in Burnley, 12·7 in Oldham, and 13·7 in Huddersfield; the highest rates were 24·7 in Leeds, 26·4 in Preston, 26·9 in Sheffield, and 31·1 in Liverpool. The 4727 deaths included 1250 which were referred to the principal zymotic diseases, against 796 and 1127 in the two preceding weeks; of these, 994 resulted from diarrhœa, 74 from whooping-cough, 57 from measles, 53 from diphtheria, 42 from "fever" (principally enteric), 30 from scarlet fever, and not one from small-pox. No death from any of these diseases was recorded last week in Halifax; in the other towns they caused the lowest death-rates in Burnley, Huddersfield, and Gateshead, and the highest rates in Birmingham, Salford, Liverpool, Preston, and Sheffield. The greatest mortality from measles occurred in Portsmouth and Plymouth, from whooping-cough in Swansea, Salford, and Preston, and from diarrhœa in Croydon, Birmingham, Leicester, Liverpool, Preston, Sheffield, and Leeds. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 53 deaths from diphtheria included 26 in London, 4 in West Ham, 4 in Birmingham, and 3 in Leeds. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and only two small-pox patients were under treatment in the Metropolitan Asylum Hospitals on Saturday last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2241, against 2321, 2326, and 2293 on the three preceding Saturdays; 187 new cases were admitted during the week, against 232, 224, and 201 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 174 and 171 in the two preceding weeks, rose again last week to 196, and were 30 above the corrected average. The causes of 45, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Salford, Leeds, Newcastle-upon-Tyne, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Birmingham, Liverpool, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·0 and 19·8 per 1000 in the two preceding weeks, further declined to 18·1 during the week ending August 20th, and was 3·9 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Edinbugh and 16·7 in Dundee to 20·4 in Leith and in Perth and 27·5 in Paisley. The 546 deaths in these towns included 70 which were referred to diarrhœa, 24 to whooping-cough, 9 to "fever," 7 to scarlet fever, 6 to measles, and 2 to diphtheria. In all, 118 deaths resulted from these principal zymotic diseases, against 134 and 136 in the two preceding weeks. These 118 deaths were equal to an annual rate of 3·9 per 1000, which was 1·9 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had increased from 55 to 80 in the four preceding weeks, declined to 70 last week, of which 32 occurred in Glasgow, 11 in Paisley, and 9 in Dundee. The 24 deaths from whooping-cough exceeded by 7 the number recorded in the preceding week and included 15 in Glasgow and 5 in Aberdeen. The deaths referred to different forms of "fever," which had been 1 and 5 in the two preceding weeks, further rose to 9 last week, of which 7 occurred in Glasgow. The 7 fatal cases of scarlet fever showed a decline of 5 from the number in the preceding week and included 5 in Glasgow and 2 in Aberdeen. The deaths from measles, which had declined from 25 to 13 in the three preceding weeks, further fell to 6 last week, of which 2 occurred in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 79 and 71 in the two preceding weeks, rose again to 80 last week, and exceeded by 18 the number in the corresponding period of last year. The causes of 25, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·9 and 25·5 per 1000 in the two preceding weeks, declined again to 21·8 during the week ending August 20th. During the past four weeks the rate of mortality in the city has averaged 23·8 per 1000, the rate during the same period being 19·8 in London and 17·8 in Edinburgh. The 146 deaths registered in Dublin during the week under notice showed a decline of 25 from the number in the preceding week, and included 28 which were referred to the principal zymotic diseases, against 27 and 31 in the two preceding weeks; of these, 22 resulted from diarrhœa, 3 from "fever," 1 from measles, 1 from scarlet fever, 1 from whooping-cough, and not one either from small-pox or diphtheria. These 28 deaths were equal to an annual rate of 4·2 per 1000, the zymotic death-rate during the same period being 6·3 in London and 1·2 in Edinburgh. The fatal cases of diarrhœa, which had increased from 4 to 19 in the four preceding weeks, further rose to 22 last week. The deaths referred to different forms of "fever," which had been 5 and 3 in the two preceding weeks, were again 3 last week. The mortality from scarlet fever and from whooping-cough showed a decline from that recorded in the preceding week. The 146 deaths in Dublin last week included 49 of infants under one year of age, and 30 of persons aged upwards of sixty years; the deaths of infants exceeded the number registered in any recent week, while those of elderly persons showed a decline. Five inquest cases and 4 deaths from violence were registered, and 43, or nearly a third, of the deaths occurred in public institutions. The causes of 5, or more than 3 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

FLEET-SURGEON ANTHONY GORHAM, M.D. R.U.I., has been placed on the retired list with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Surgeon Edward Cuffey has been allowed to withdraw from Her Majesty's Naval Service with a gratuity.

The following appointments are announced:—Staff-Surgeon B. C. E. F. Gunn to the *Severn*. Surgeon C. S. Bennetts to the *Halcyon*.

ROYAL ARMY MEDICAL CORPS.

Major W. E. Berryman proceeds from Portsmouth to Bulford Camp for duty during the manœuvres. Lieutenant-Colonel W. B. Allin officiates as Principal Medical Officer, Aldershot District, during the absence of Surgeon-General T. F. O'Dwyer with the Northern Army at the manœuvres. Lieutenant-Colonel W. T. Johnston is placed under orders for India. Captain R. J. W. Mawhinny is transferred to Dublin.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel A. S. Reid, Bengal Establishment, 38th Dogra Regiment of Bengal Infantry, is appointed Principal Medical Officer, Kohat-Kurram Force, vice Brigade-Surgeon-Lieutenant-Colonel Murphy, on leave. Surgeon-Captain Jordan, Officiating Deputy Sanitary Commissioner, Metropolitan and Eastern Bengal Circle, is granted furlough for twelve months. Surgeon-Captain Morwood, Civil Surgeon, Shahjahanpur, is appointed to hold Visiting Medical Charge of Hardoi in addition to his other duties. The services of Surgeon-Lieutenant-Colonel Mair (Bengal) are placed temporarily at the disposal of the Government of Bengal for employment as Officiating Inspector-General of Jails, Bengal.

The Queen has approved of the following admissions to Her Majesty's Indian Medical Service:—To be Surgeon-Lieutenants: Thomas Hunter, Walter Rothney Battye, Harold Budgett Meakin, George Hutcheson, William Glen Liston, Harold Boulton, Richard William Anthony, Ernest Frederick Gordon Tucker, George Edward Stewart, Frank Stuart Corbitt Thompson, Thomas Shepherd Novis, John William Watson, Herbert Joseph Richard Twigg, and Charles William McGillicuddy Orpen.—*London Gazette*.

ROYAL ARMY MEDICAL CORPS.

The following is the list of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London:

	Marks.		Marks.
F. Warren	2538	G. W. G. Jones	2183
J. E. Hodgson	2617	J. W. H. Houghton	2117
H. P. W. Barrow	2602	H. S. Taylor	2101
M. H. G. Fell	2511	A. L. Scott	1991
T. C. Lauder	2415	J. W. Leake	1969
J. G. Gill	2292	R. H. Lloyd	1935
W. B. Winkfield	2266	D. E. Curme	1892
G. H. Goddard	2211	G. M. Goldsmith	1848

THE INDIAN MEDICAL SERVICE.

The following is the list of candidates who were successful at the competitive examination for the Indian Medical Service, held in London on August 5th:

	Marks.		Marks.
J. C. H. Leicester	3179	L. E. L. Parker	2336
H. Innes	2888	T. S. Ross	2316
W. S. Willmore	2660	J. N. Walker	2278
L. T. R. Hutchinson ...	2604	D. E. Kemp	2274
A. C. Walter...	2553	V. H. Roberts	2259
C. Hudson	2523	J. E. Robinson	2215
A. M. Fleming	2469	G. P. T. Groube	2131
H. M. Cruddas	2460	G. King	2095
C. F. Weinman	2452	P. P. Atal	2091
E. L. Ward	2411	W. McM. Pearson	2027

MEDICAL HISTORY SHEETS FOR BARRACKS.

Acting on the recommendation of his medical advisers the French War Minister has decided on issuing orders that in future at all military stations a special sanitary register is to be kept up for each separate building occupied by soldiers, the object of the new ordinance being the accumulation of information likely to assist medical officers in their efforts to extinguish epidemic and contagious diseases. Each "barrack sanitary register" is to consist of two parts, the first part being devoted to a detailed description of the building, including general plan, altitude, style of architecture, aspect, material employed, cubature of rooms, date of erection, previous history of site, nature of soil, and subsoil, source and quality of water-supply, system of drainage with plans of drains old and new, sanitary condition of neighbourhood, &c., while in the second and more novel part of the register the medical history of each building is to be carefully kept up to date. Amongst many other things there are to be noted daily the number of occupants in each room, the number of men reporting sick together with the diseases they are found to be suffering from, the occurrence of epidemic or contagious diseases, the precise situation of the beds occupied by the affected soldiers, &c. The nature and date of all repairs are also to be recorded, as a full description is to be given of all sanitary measures which may be adopted. There can be no doubt that a register of this sort would afford valuable information in many doubtful cases and should similar records be deficient in our own barracks it would, we venture to think, be well to introduce them without delay.

THE SPANISH-AMERICAN WAR.

The Spanish-American war is happily a thing of the past. The Americans will now have to settle with the insurgents and natives of the places which they have already taken or which will be hereafter ceded to them. As far as Cuba is concerned there seems to have been a serious administrative failure on the part of the War Department at Washington. The state of things at Santiago, together with the alleged want of proper arrangements on board the transports conveying the sick and wounded from Cuba, the insanitary position and wretched condition of the sick camps at Montauk Point and other places in America whither the sick are being sent, have naturally given rise to very serious complaints. If the condition of things be as bad as is described it would seem that there was a state of unpreparedness on the part of the Americans which was as surprising as it was lamentable.

A FRENCH MEDICAL OFFICER ACCOMPANIES GENERAL KITCHENER'S ARMY.

Dr. Duval, surgeon-major of the 125th regiment of the line, has received permission to accompany the British and Egyptian forces in their advance on Khartoum. This officer, who is a Knight of the Legion of Honour, has already enjoyed an opportunity of making himself acquainted with the way in which our army medical affairs are managed on active service, having been present during the late operations against the Afridis on the Hindu Kush frontier.

DEATHS IN THE SERVICES.

Deputy Inspector-General of Hospitals E. W. Bawtree, Surgeon-Major (retired), at Mistley Hall, Essex, on August 13th, in his eighty-first year. He entered the Army in 1843, became Surgeon-Major in 1866, and retired with the honorary rank of Deputy Inspector-General in 1872. He served in the New Zealand War and acted as Senior Medical Officer in Taranaki from May, 1865, to April, 1866. He also served in the Abyssinian expedition as Principal Medical Officer of the British troops, 2nd Division, from March, 1868, to the termination of the campaign (medal).

BACTERIOLOGICAL LABORATORIES IN INDIA.

To the Editors of THE LANCET.

SIRS,—In a recent issue of THE LANCET I read the following:—

When the recent outbreak of plague occurred at Calcutta it was a matter of obvious importance that the exact nature of the disease should be determined with the least practicable delay. Happily for the Government of Bengal, the services of M. Haffkine were available and he was able to report, as the result of a bacteriological examination, that the outbreak was due to true bubonic plague. We have heard a great deal about the establishment of bacteriological institutes or laboratories in India; now here was an occasion in which a bacteriological laboratory in Bengal would have been of the greatest use, and we are glad to notice that the *Englishman* of Calcutta has called attention to the subject.

To the credit of the Municipal Commissioners of Calcutta be it said that, on the representations of the late medical officer of health, Dr. Simpson, they provided and equipped a bacteriological laboratory, so that I was able to work out my first case of plague bacteriologically. I obtained the bacillus in pure culture and sent two agar slopes to Professor Haffkine in Bombay for confirmation of my results, as I was advised that Government would not take the responsible step of declaring the city an infected area without the opinion of an expert. The post-mortem examination was absolutely typical of plague. I know of no other disease which produces such pathological features—huge hæmorrhages extending from an affected femoral gland up into the abdomen behind the peritoneum and half way down the thigh, and petechial hæmorrhages on the heart and other viscera. I made cultures from the gland, spleen and heart's blood. From the cultures I inoculated two guinea-pigs subcutaneously in the thigh. Both died four days later with buboes and hæmorrhages and I got the same bacillus in culture and under the microscope from them. I also obtained it growing in stalactites from ghee (clarified butter) floating on the surface of a flask of bouillon. So I had pathological, microscopic, and cultural proof, which was further supported by the clinical history I had obtained, before I heard from Professor Haffkine. I may add that my investigations were closely followed by Surgeon-Colonel T. H. Hendley, C.I.E., Inspector-General of Civil Hospitals, and Surgeon-Major H. J. Dyson, F.R.C.S. Eng., Sanitary Commissioner, who were satisfied with the accuracy of my results. I am, Sirs, yours faithfully,

J. NIELD COOK, D.P.H.,
Health Officer.

Municipal Office, Calcutta,
August 3rd, 1898.

BERI-BERI AND RICE.

To the Editors of THE LANCET.

SIRS,—*Apropos* of Dr. W. K. Hunter's very interesting report on two cases of beri-beri in the recent issue of THE LANCET[1] I would like to offer a criticism. Though beri-beri is not so common in India as is generally supposed yet it is frequently met with in Madras and Burma. In Calcutta and Bengal generally I only know of cases among Chinese in Calcutta. Till recently a lamentable confusion has existed in India about this disease. What is sometimes called beri-beri in Assam and Ceylon is now known to be ankylostomiasis. Cases of anæmic dropsy due to malaria have even been mistaken for beri-beri, whereas anæmia is neither a necessary nor important symptom of the disease. To return, however, to Dr. Hunter's paper. If his discovery of the white staphylococcus (identical with that of Pekelharing and Winkler) in rice be confirmed and found in other cases it will go far to prove Dr. N. Macleod's theory of beri-beri being not a "place" but a "food" disease. I have before me as I write Vordermann's elaborate report in Dutch on the subject of rice and beri-beri (*vide* also Dr. Eikjman's article in *Janus*, August, 1897); there it is shown that in many Javan prisons where "red" rice was used there was no beri-beri, whereas when "white" rice (i.e., rice with the red cuticle

[1] THE LANCET, June 25th, 1898.

Digitized by Google

removed) was issued much beri-beri existed among the prisoners. No other factor, according to Dr. Vordermann's report, was of any importance compared with the distinction between "red rice" and "white rice." It is not easy to see how the removal of the red cuticle of rice could influence the incidence of a disease like beri-beri. The nitrogenous value of the rice would be practically equal in both cases, so the experience of the abolition of "kakkee" in the Japanese Navy does not help us. Moreover, in Bengal gaols, where the population is almost entirely a rice-eating one, we never get beri-beri, though the jail code insists most strongly on the issue of only thoroughly cleaned (white) rice (*vide* my "Manual of Jail Hygiene," p. 36). Can it be that the organism of beri-beri only attacks rice from the further East? I would ask medical officers of ships carrying Lascars to inquire the source of the rice issued to the crews. Is it from an Indian port or from Rangoon, Siam, or further East? There may be something in this suggestion. But no matter where the rice comes from how does the germ escape being killed by cooking? It is not easy to understand how any microbe could withstand the boiling which rice gets when cooked according to Indian methods. Has Dr. Hunter found the staphylococcus in cooked rice? Or if so, could the germ not have found its way into the food when exposed in plates on the theory that beri-beri is a *place* disease, as Manson holds? Manson, by-the-bye, in his Tropical Diseases Manual appears to have given up the organism of Pekelharing, and Glogner's amœba has so far little evidence. Surely the prolonged stay of beri-beri in the Richmond Asylum has given Dublin bacteriologists an opportunity of studying the organism of this disease. If so I have seen no accounts published. Perhaps Mr. C. Norman's paper at the Edinburgh meeting of the British Medical Association will afford the needed and expected light.—I am, Sirs, yours faithfully,

W. J. BUCHANAN, B.A., M.B., B.Ch., Dip. S. Med. Dub.,
Surgeon-Captain, I.M.S., Superintendent Central Jail, Dacca.

Dacca, Bengal, August 2nd, 1898.

BLOOD GRANULES.

To the Editors of THE LANCET.

SIRS,—May I be allowed to point out an error in the record of my demonstration of blood granules[1]? The relation of granules to red cells in Bright's disease and chronic gout is there given as from 1 to 30 to 1 to 40. It should have been from 1 to 1 to 1 to 5, as one of the chief points of the demonstration is that in pathology the granules are very numerous in Bright's disease and chronic gout, conditions in which all observers agree that there is much uric acid in the blood; and, on the other hand, are very scanty, from 1 to 30 to 1 to 40, in fever, in which observers again agree that there is little or no uric acid in the blood.

I am, Sirs, yours faithfully,

Brook-street, W., August 20th, 1898. ALEXANDER HAIG.

APOTHECARIES' HALL OF IRELAND.

To the Editors of THE LANCET.

SIRS,—Your Irish correspondent was in error in stating in THE LANCET of August 13th, 1898, that "the first examination by the Apothecaries' Hall of Ireland in conjunction with the Royal College of Surgeons in Ireland which has been held since the decision of the General Medical Council and the appointment of the new board of examiners has just concluded." Except in the cases of former candidates the Royal College of Surgeons in Ireland has ceased to examine in conjunction with the Apothecaries' Hall.

I am, Sirs, yours faithfully,

August 23rd, 1898. G. F. BLAKE.

"EUNATROL."

To the Editors of THE LANCET.

SIRS,—Messrs. Zimmer and Co. are obliged for the notice contained in THE LANCET of July 30th on their exhibits at the Edinburgh exhibition. With regard to the criticism on the part of your reporter about the name "eunatrol" they say: "These remarks we cannot but find very much out of place. Apart from the fact that the name of 'eunatrol' abbreviates the description of pure oleate of sodium by three words we have here an *absolutely* pure oleate of sodium. Oleate of sodium is by no means a new thing—its rancid and objectionable smell, however, made it practically useless. Our chemically pure oleate of sodium is a new invention, which we venture to say also deserves a special name."

We remain, Sirs, yours truly,

Pro W., B. AND CO.,
W. BREDT.

Lime-street, E.C., August 22nd, 1898.

*** The "reporter" in question was the chemist in charge of our analytical department. So far from finding his criticism out of place we consider it, on reflection, very apt.—ED. L.

[1] THE LANCET, August 20th, 1898, p. 515.

THE SOUDAN CAMPAIGN.

(FROM OUR SOUDAN CORRESPONDENT:)

SURGEON-GENERAL TAYLOR arrived a few days ago from England and the disposition of the various medical units was arranged. There are to be twelve field hospitals under the charge of Majors of the Royal Army Medical Corps, a 100-bedded hospital at the Atbara, and a 300-bedded one at Abadia. The hospitals on the lines of communication will be established on the various steamers which will run between the front and the base hospitals, and a medical officer will be on board the new gunboats which will play an important part in the bombardment of Omdurman. The troops from Darmali will be placed on board steamers there and taken up to Shatluka where the two brigades will concentrate, and from hence the general advance will be made. The cavalry and the Royal Artillery have each a field hospital allotted to them and this time there will be no want of medical officers or material. The Royal Engineers have been hard at work on the sun covers for the stretchers and a very good shaded stretcher has been made on the same plan as the Indian "dandy," on which severe cases can be moved with the minimum of jolting and exposure. Several new sets of capital instruments (aseptic) with sterilisers have been served out to the field hospitals and plenty of antiseptic dressings are available. The great difficulty will be the water for drinking purposes as we near Khartoum, as it is practically impossible to carry enough filters to supply the amount of filtered water needed for both brigades, but every precaution will be taken and the water will be boiled whenever practicable. It is intended to have a Pasteur filter for the field hospitals, but where transport is such a consideration it is not always possible to carry out good intentions. The health of the troops continues good and with the exception of a few scattered cases of enteric fever there is practically no sickness, but the men are getting weary of the forced inactivity and a move will do us all good. The one item which has not been decided on yet, so far as I know, is a hospital ship. This ought to be arranged for, as if we have any casualties and much sickness a properly equipped steamer at Alexandria with all necessary medical comforts and nursing appliances so that the patients could be put on board and taken straight to Netley would be of inestimable value. This ship should be entirely for the sick and wounded and should be ready at the close of the campaign. It is to be hoped that the general public will realise that upon this occasion the medical arrangements have been properly thought out and every item carefully looked after and that if there is any breakdown it will not be the fault of the officers or men of the Royal Army Medical Corps.

Fort Atbara, August 5th, 1898.

ABERDEEN HOSPITAL SATURDAY.—The balance at credit of the Aberdeen Friendly Societies' Hospital Saturday Fund has been allotted as follows:—Royal Infirmary, £600; Sick Children's Hospital, £150; Dispensary, £150; Convalescent Hospital, £100; District Nursing Association, £65; Ophthalmic Institution, £50; Hospital for Incurables (adults), £50; Hospital for Incurables (children), £10; total £1175. In virtue of these contributions the general committee have nominated 14 life managers for the Royal Infirmary, 6 for the Sick Children's Hospital, 6 for the Dispensary, and 1 each for the Ophthalmic Institution and the Morningside Hospital (Incurables).

THE ABUSE OF NURSING CHARITIES.

(FROM OUR SPECIAL COMMISSIONER.)

FROM evil good sometimes springs, and it does seem as if the medical profession has every reason to felicitate itself on the action taken by the "Maternity Charity and District Nurses' Home" of Plaistow. But for the aggressiveness of this so-called charity the profession in the east London suburbs would have remained in its former condition of apathy. Now, however, the spirit of organisation has spread, the necessity of resistance and self-defence is recognised, and a strong medical union is in course of formation. In August last year the Bishop of Colchester addressed an appeal to the *Times* for subscriptions to aid in establishing a branch of the Plaistow Nurses' Home at West Ham. Thus the grievance, which was the cause of many complaints at Plaistow, threatened to spread over to other districts. To Mr. Charles Allen is due the credit of having taken the initiative in organising resistance. He sent out numerous circulars, called personally on many of his medical colleagues, drew up a protest, and succeeded in obtaining the signatures of 51 medical practitioners to this manifesto. Several meetings of medical men were held and finally it was decided to form a union which is known as the "East Suburban Medical Protection and Medico-Ethical Society, Limited." It is a pity that at its start in life this organisation should have encumbered itself with so unwieldy a title. The word "union" is the only word necessary and it is just the one word which has been left out. The society, it will be seen, is a union. It was only necessary to add that it was a medical union and to give its geographical limitation. The title East Suburban Medical Union would have better met the case. However, this is quite a minor matter, and when the society was first started no one seems to have foreseen how rapidly it would develop into a genuine union. Indeed this is the most instructive and hopeful phase of the whole question. A grievance concerning a nursing institution brings members of the profession together, and thereupon they at once discover that there are scores of other grievances, that the position of medical men is threatened from all sides, that resistance by the individual is impossible, and the formation of a strong union is the only policy offering any chance of success.

Of course, the first action taken related to the grievance which had brought members of the profession together. A deputation was appointed to wait upon the Plaistow Maternity Charity to explain, firstly, that this charity was breaking its own rules by charging fees and that its nurses, whether trained or only serving an apprenticeship, were competing with the medical profession. Many persons who were in the habit of paying guinea midwifery fees to their medical advisers now called in one of the nurses, who only charged 5*s*. The Plaistow Maternity Charity obtains premiums of from £15 to £40 from the women who join this institution to be trained as nurses, then fees are obtained from the patients, and, finally, on the pretext that this is a charity, large donations are collected from the public. Under such circumstances there is no reason why the institution should not in the course of time be converted into a paying commercial concern. How can medical men or trained professional nurses who have no other source of income but their fees compete against an institution which not only receives fees from the patients but premiums from its nurses and large subscriptions from the public? All the medical men complain of this competition. They even accuse the nurses of touting and of interfering with the treatment of their patients. Thus in a house let out in tenements there may be two families. A medical practitioner is attending one family and a nurse from the Plaistow Nurses' Home is attending the other family. In the medical man's absence the nurse will give advice gratuitously to the medical man's patients. This may be done from motives of kindness and good nature, but it interferes with the medical treatment and advertises the fact that the nurses cost less than the medical practitioner. Also this interference may at times injure the patients, for it must be borne in mind that these nurses are often raw girls recruited from the uneducated classes who have paid their premiums but have not yet learnt much about nursing. Of course, any help given gratuitously to the extreme poor is better than no help at all; but when fees are charged and fully qualified practitioners are driven away and replaced by nurses the question as to the ability and knowledge possessed by these nurses may very justifiably be raised. Ought untrained nurses who are just beginning their apprenticeship to be sent to private patients?

It was on Feb. 11th last that the deputation of medical men waited upon the committee of the Plaistow Maternity Charity. In answer to their protest they were subsequently informed that the nurses' midwifery fee would be raised from 5*s*. to 10*s*., and that everybody would be forced to pay unless upon inquiry it could be proved that the breadwinner of the family was not earning more than £1 per week, or if a clergyman or a medical man asked that the nursing should be done gratuitously. Thus the Plaistow Maternity Charity has deliberately set itself to work to tap the sources of income on which the poorer practitioners rely—namely, patients whose earnings are above £1 a week and who can therefore be made to pay a midwifery fee of 10*s*. It is true that a promise has been given not to allow touting, and that this is now against the rules of the Plaistow Maternity Charity. The zeal, however, of subordinates renders this rule ineffectual. Thus, for instance, a short time ago a medical practitioner arranged to take a midwifery case and the fee was to be one and a half guineas. The patient said she proposed to engage a nurse from the Plaistow Maternity Charity and went there for that purpose. After having made the necessary arrangements the attendant who took down the name and address inquired what the applicant proposed to do about a midwife. The lady replied that having engaged the services of her usual medical attendant she did not require a midwife. In spite of this, and just as the lady was leaving and going downstairs, the attendant called out after her, "Do you really think a doctor is necessary?" Here, then, was a deliberate effort made to replace a fully qualified practitioner by a nurse who was to undertake this midwifery case though her qualifications might well be open to question. It was an attempt to undercut a medical practitioner by offering a nurse who would take a much smaller fee. The acceptance of the smaller fee by the nurse is economically possible because the institution from which she comes is supported by charitable donations. Thus instead of helping the poor this charity is in such cases working to impoverish medical men. A nurse whose education as a nurse has cost her from £15 to £40 is sent to replace a medical practitioner whose medical education has cost him from £600 to £1000. No wonder that the nurse can take a smaller fee, particularly when she lives at the expense of a charitable institution.

At the same time it is freely acknowledged by the medical practitioners that the nurses from the Plaistow Maternity Charity and District Nurses' Home are very useful, that they do excellent work, and that they would be most worthy of general support if they would not go beyond their legitimate field of action. Their business should be to nurse the poor gratuitously, but to nurse the poor alone. If they nurse persons who can afford to pay then they are unfairly competing against professional nurses who depend for their livelihood on the fees which well-to-do persons can give. The position of a well-trained nurse is as worthy of consideration as that of any other member of the community, and it is gross abuse that money given for charitable purposes should be employed to ruin so estimable and useful a calling as that of a trained nurse. Yet many high-class, or at least wealthy, people in the eastern suburbs of London employ nurses from the Plaistow Maternity Charity for various kinds of illness. For this ordinary nursing the nurses are not allowed to take any payment, but when the people who employ them have means they generally make a donation to the charity. Such donations are payments in disguise. From every point of view this is a heinous system. A person is ill; he has means and he wants a nurse. The only honourable course to pursue is to employ a trained nurse and pay the full market value of her services. Instead of this the patient sends to a charity, takes a nurse away who ought to be attending to the poor—thus defrauding the poor of the help which this nurse could give them and for which charitable persons have subscribed their money. The rich man, after having been nursed gratuitously by the charity nurse, now steps forward as a philanthropist by making a donation to the charity, giving probably a sum inferior to that which an independent trained nurse would

Digitized by Google

have cost him. Far from being a philanthropist, this man has been favouring a system of undercutting the market for trained nursing, thus helping to ruin the trained nurses. On the other hand, he has withdrawn from the slums of London one of the nurses available for the nursing of the extreme poor. He has saved a few shillings at the cost of the poor and at the cost of the trained nurses; and yet he appears on the list of donors to a charity, and those who are not acquainted with the inner workings of the transaction would look upon him as a philanthropist. This has happened over and over again, and it is quite possible that many who have committed this abomination are in no wise conscious of having done anything wrong. In this commercial community the instinct to buy in the cheapest market is so strong that it is done automatically and without reflection as to the moral consequences and responsibilities. But while it is thus scarcely surprising that some members of the general public should with thoughtless ignorance act in this manner it is most astonishing that a charitable and nursing institution should lend itself to the perpetration of such gross abuse. Here is the Plaistow Maternity Charity taking fees of from £15 to £40 to train poor girls as nurses, and yet it employs these very nurses to undercut the market and render the profession of nursing more and more precarious and ill-paid.

If from the question of ordinary nursing we proceed to the question of midwifery identically the same grievance will be found, only in this latter case the victim is not the trained nurse but the general medical practitioner. The charity nurse who assumes the functions of a midwife does for 5*s*.—now for 10*s*.—what the medical practitioner has been in the habit of doing for a guinea and upwards. Persons who formerly found no difficulty in paying the higher fee avail themselves of the charity to save their money. Donations given to the charity in order to help the extreme poor thus serve to economise the resources of the well-to-do and to impoverish the medical practitioners. But even with the poor there is no need of these midwives. In East London there are unfortunately many fully qualified medical men who are reduced to accepting half-guinea midwifery fees. Indeed, one or two have been known to take as little as 7*s*. 6*d*. Surely anyone who cannot afford such a sum for so serious a matter is justified in calling in the Poor-Law medical officer. Therefore where does the need of the midwife come in? Nursing and monthly nursing are often much needed and this is the proper field of action for a charity if the people are really poor. Instead of thus limiting their action to cases where charitable help is really needed the Plaistow Maternity Charity sends out its nurses to act as midwives to families who can afford to pay them 10*s*., thus taking the bread out of the mouths of the poorer practitioners and depriving the patients of the services of a fully-qualified medical attendant.

Such is the grievance which has brought the members of the medical profession together in east suburban London. It will be seen ultimately that as soon as they began to discuss this matter they discovered that there were various other complaints and difficulties which also required careful and energetic handling. Hence a union has grown out of this trouble and its action promises to be fruitful in the bringing about of many reforms which will be to the advantage of the general public and of the medical profession.

(To be continued.)

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Immediate Evacuation for Plague.—The Mortality in the Bombay Presidency.—The Enormous Plague Expenditure.

PALANPORE city was visited by plague in February, 1897, and a mild epidemic lasted until May. It became reinfected from Bombay in August. In the first outbreak few measures seem to have been adopted and during the second outbreak at first neither vigour nor thoroughness characterised the steps taken. On Nov. 2nd last the city was evacuated and by the end of the month the epidemic was practically at an end. House-to-house visitation had been a failure because of the objection to segregation and hospital treatment and also to the apathy of the search parties. Eight thousand people turned out into huts built by themselves. So far as the city is concerned the cessation of plague may be explained by the rapid subsidence occurring in the natural course of an epidemic, the outbreak having lasted about its normal period; but when every freshly-infected village in the district was dealt with on this plan the death-rate was reduced from 72·9 to 60·4 per cent. The proportion of cases to population is not given, but the lowered mortality is a distinct gain, and whereas previously 25 villages had recorded 465 deaths the 27 freshly-infected villages returned only 191 deaths. It is urged by the medical officer in charge that the cases were reduced by one half and that the mortality was lowered 12·5 per cent. The expenditure is said not to have involved the crushing liabilities which weigh heavily upon many cities and districts in the Presidency. The enormous expenses incurred by the plague operations have very seriously crippled the finances of many towns and cities. The municipality at Karachi have instituted a plague tax of 3 per cent. on house and land owners which will remain in force until 1901. In Bombay large sums have had to be borrowed—the expenditure having been over 30 lakhs of rupees—which will cripple the progressive work of the municipality for years. The expenses at every place having been so out of all proportion to the result achieved it may even be stated as doubtful, if plague had been left to take its course unchecked, whether it would have been attended by any greater disaster. The general unrest and the disturbance to trade would certainly have been avoided.

A recrudescence of plague has occurred in villages near Hyderabad; the mortality at places where plague still lingers is very high. For the past week Bombay records 82 cases, 70 deaths; Karachi 23 cases, 19 deaths; Surat 107 cases, 86 deaths; Sutara 59 cases, 56 deaths; Belgaum 338 cases, 262 deaths; Dhawar 164 cases, 129 deaths; the total for the Presidency being 1096 cases and 904 deaths—a percentage of 82·4, the total deaths recorded from plague being 93,183. In Calcutta the cases still continue to be sporadic. In Bombay the deaths from plague remain at an average of about 10 a day, one district alone, called Mandvie, maintaining it in anything like epidemic proportions. The great improvement scheme for Bombay involving several millions of pounds, is likely to be postponed.

August 5th.

THE SPANISH-AMERICAN WAR.

(FROM A SPECIAL CORRESPONDENT.)

Detention Camp, Egmont Key, August 9th.

Reception and Care of Sick and Convalescent.

SINCE I last wrote we have heard of a letter in the *New York Times*, from its correspondent here, in which strictures are made upon the direction of this camp and indirectly upon Dr. H. D. Geddings. The mere suspicion of any criticism of Dr. Geddings excited the liveliest indignation among the officers who have been detained here. The facts in the matter are briefly as follows. On the arrival of the steamship *Santiago* at quarantine on July 29th we were told we would be put on this Key for detention. It was found upon inquiry that Dr. Geddings was not at the camp, having taken a sick steward that very morning to Port Tampa. He did not expect any sick to be landed here, but, on the contrary, had received positive instructions that this camp was not to be used for any such purpose, so there was no reason why he should not have been temporarily absent. He did not receive our urgent telegram until 9 P.M. on Friday. After that late hour he made arrangements for stores and many necessary things, which the sudden call for provision for 186 men (mostly sick) demanded and he had also to obtain formal permission from Washington to allow us to land and occupy the camp. He was on hand early next morning. We were landed quickly without exposure or fatigue and in an hour or two at most the sick, convalescent and well were comfortably tented and given an abundance of good food. Dr. Geddings made constant rounds among the sick and well and saw that everything possible was done for them. In an incredibly short time he had a sufficient number of hospital stewards at work and things were running smoothly.

From the first the food has been plentiful and well cooked and many delicacies have been provided for both officers and men and dispensed with a liberal hand. The camp has been kept wonderfully clean and every little detail has been

Digitized by Google

looked after by Dr. Geddings himself. After the storm he took the officers (it so happened that the tents which they occupied had suffered most) and some soldiers into his own place and tenderly cared for all. During the night of the storm the chief steward (Mr. Peck) was out the entire night attending to the sick and Dr. Geddings was up very late.

Both officers and men have improved greatly under Dr. Geddings's care and all are most thankful to him for his courteous and unremitting attention. I have shown this statement to the officers, including General Duffield, Major D. B. Wilson, Captain C. D. W. Wilcox, Lieutenant Mark L. Hersey, Major Thornton, Major Wessels, Lieutenant J. C. Reeves, and others, who heartily endorse what I write.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Bangor Cottage Hospital.

FROM the annual report of this seaside hospital and convalescent home I find that there were 60 patients during the past year. The addition of new bath-rooms and improved sanitary arrangements has proved of the greatest advantage. The Society for Providing Nurses for the Sick Poor, Belfast, has sent 28 patients. The local medical men are thanked for voluntarily giving their services.

Fever in Armagh.

At a meeting of the board of guardians of Armagh, held on August 16th, it was reported that a third outbreak of fever had occurred in the Irish-street Barracks of the constabulary within one year. It seems that repeated representations had been made to the authorities by the local sanitary bodies to have the condition of matters remedied, but so far no effectual steps have been taken. One of the guardians proposed a motion, which was adopted, that the attention of the authorities should again be called to the condition of this barrack and that they be requested to provide a proper sanitary building for the police stationed there.

Sanitary Condition of Armagh.

At a special meeting of the Town Commissioners of Armagh, held on August 19th, convened to take steps regarding the insanitary state of many parts of the city as disclosed by Mr. Gray's report, which was before the board at a previous meeting, Mr. Gray indicated a large number of houses as being unfit for human habitation. Other dwellings were insanitary but might be made fit for human habitation. Practically, the report meant the closing of at least 100 houses, leaving perhaps from 400 to 500 persons without a home. It was decided to adjourn the consideration of that part of the report dealing with houses unfit for habitation until the September meeting and the landlords of those houses which Mr. Gray believed could be made fit to live in were ordered to be served with a specification of the work which the Commissioners required to be carried out.

Belfast Royal Hospital.

At the quarterly meeting, held on August 22nd, it was reported that during the previous three months there had been 556 intern and 6571 extern cases. A sum of £315 15*s.* 10*d.* had been realised by Hospital Saturday. At the close of the previous quarter the debt against the hospital amounted to £1544 18*s.* 11*d.* Since then the receipts from all sources had been £2007 1*s.* 0*d.* and the expenditure had been £2334 0*s.* 10*d.*, thus increasing the debt by £326 19*s.* 10*d.*, making the amount now owing by the hospital at the end of the eleventh month of the financial year £1871 18*s.* 9*d.* Owing to the rapidly increasing population of the city the demands upon the hospital are becoming more pressing and call for greater support and generosity from every section of the community. Professor Whitla, Dr. O'Neill and Dr. A. B. Mitchell were all re-elected medical attendants of the institution.

Visit of Delegates from the Dublin Health Congress to Belfast.

On August 22nd a company of delegates to the Dublin Public Health Congress, numbering some 65, paid a visit to Belfast on the invitation of the Lord Mayor and Lady Mayoress of that city. They were met and cordially welcomed at the railway station on their arrival by the local reception committee and were taken round various parts of Belfast, visiting the fire brigade station, the shipbuilding works at Queen's Island, the filter works of the Belfast water commissioners, &c. The Lord Mayor (Alderman Henderson, M.A.) entertained the delegates most hospitably to luncheon at the Grand Central Hotel. They returned in the evening to Dublin.

Irish Academic Honours to Scotch Medical Men.

The Royal College of Physicians of Ireland has conferred honorary Fellowships on Dr. A. Crum Brown of Edinburgh and Dr. Matthew Hay of Aberdeen. The honorary diploma in State Medicine has at the same time been conferred upon Sir Henry Littlejohn of Edinburgh.

Death by Lightning in the County Cork.

Last Wednesday night and Thursday morning a singularly violent thunderstorm passed over the south of Ireland. The flashes of lightning were so vivid and occurred at such short intervals that many people believed their houses to be on fire. The heavens were repeatedly illuminated and the smallest objects could be clearly discerned on the thoroughfares. The loud thunderclaps reverberating in quick succession caused considerable alarm to the timid. In many places a stampede occurred amongst cattle and several were killed by the lightning. Farmers have also to bewail considerable damage to crops, which had been particularly promising. It is stated that a young man, twenty-five years of age, residing near Macroom, was struck by the lightning. He was sleeping with his brother and in the course of the night, being greatly alarmed, got out of bed and walked from room to room. After a time he returned to bed and soon afterwards his brother spoke to him, but as he received no reply he endeavoured to arouse him, and then found that he was dead. Later it was ascertained that the floor of one of the rooms had been torn up, apparently by a thunderbolt, and it was assumed that the poor young man was struck by the electric fluid whilst wandering through the house, but the innate probabilities of the case are that fear acting on a weak heart was the immediate cause of death.

Resignation of a Medical Officer.

Dr. Thomas Nedley has resigned his appointment of surgeon to the household of the Lord Lieutenant of Ireland.

August 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Avian and Human Tuberculosis.

A PERFECT wealth of communications dealing with this subject has been laid before the Congress now sitting, but perhaps the most interesting researches are those of M. Nocard. He reminded his hearers that at first sight tuberculosis in birds appears to be very different from that in human beings. The fowl cannot be infected by inoculation with tuberculosis from a human being any more than from a bovine. On the other hand, certain animals, such as the dog and the guinea-pig, which are most susceptible to infection from both human and bovine tubercle, are very refractory to avian tubercle. If, however, a guinea-pig be inoculated in its peritoneal cavity with tuberculous matter from a bird it often dies, showing a special kind of lesion. A rabbit becomes tuberculous in a very different way whether the tuberculous matter be taken from a bird or from a human being. But after the inoculation has been passed through a series of animals the resulting lesions become similar. Horses, which are very fairly resistant to experimental tubercle, contract under natural conditions, tuberculosis rather commonly. Two types of the disease exist which have for a long time been distinguished clinically as the abdominal type and the pulmonary type. Recently M. Nocard has been able to establish the fact that these two forms answer to the two different origins of the tubercle bacillus. The pulmonary form is set up by the bacillus of human tubercle and the abdominal form by the avian variety. He has also found that the sputum of a tuberculous patient will kill a rabbit by inoculation but only very rarely a guinea-pig. Cultures made after several passages through a rabbit were exactly similar to those obtained from a tuberculous bird. The eating of tuberculous poultry is therefore not without danger. M. Nocard recalled numerous instances where poultry-yards had been infected by tuberculous people employed to look after them, but it is known that fowls which pick up

Digitized by Google

tuberculous sputa do not themselves become tuberculous. M. Nocard attempted to alter the bacillus of human tuberculosis by sowing it in the peritoneal sacs of poultry. He enveloped a glycerinated bouillon culture in a little bag of collodion and inserted it into the peritoneal cavity. After leaving it there for from five to eight months he withdrew it and found it to contain a sort of paste made up of bacilli. Cultures made from this paste grew extremely well, but a very interesting fact was observed. The bacillus had lost its human characteristics and assumed avian characters. It grew at high temperatures and the cultures did not present the characteristic frayed-out clumps. The bacillus was not yet fatal to fowls, and it was not until two or three passages through fowls and after from four to six months' time that it attained virulence enough to produce tuberculosis in these birds. In one case, however, a fowl suddenly contracted tubercle at the end of eleven months from the introduction of the collodion bag and at the post-mortem examination it was found that the bag had burst, thus showing that the development of the bacillus had proceeded far enough at the moment of the bag breaking to produce tubercle in the fowl. These experiments, M. Nocard considers, are a proof that human and avian tubercle are only two different varieties of the same disease.

The Congress of Neurology.

The Congress of Alienists and Neurologists now sitting at Angers have decided that the next meeting shall be held at Marseilles in April, 1899, with M. Doutrebente as President.

Transmission of Toxins from the Fœtus to the Mother.

At the meeting of the Academy of Sciences held on August 1st M. Charrin read a paper on the above subject. He stated that after a series of experiments he has succeeded in poisoning pregnant animals with diphtheria toxin by injecting this toxin into the fœtus while still *in utero*. He plans his incisions so as to avoid the placenta and distributes the doses among the various fœtuses. Abortion almost invariably takes place, but it is sometimes delayed long enough to allow the poison to circulate in the placenta. The nature of these microbial principles, the structure of animal membranes, and the difficulties of dialysis do not permit the question of transmission from the fœtus to the mother to be answered on merely *a priori* grounds. M. Charrin has not been able to obtain by this method a vaccine which is inimical to either diphtheria or tetanus, but in some few cases he has been able to augment the resistance of the mother to the bacillus pyocyaneus by using the corresponding toxin. The toxin employed, however, is very weak. He considers that by the process of dialysis or of selection the maternal economy absorbs weak doses of toxin or of certain portions of the toxin. From that time the maternal economy becomes resistant and Colles's law is founded on analogous facts. If in place of an artificial intra-fœtal injection it be supposed that things occur as they do in syphilis, if it be admitted that the fœtus receives a virus transmitted by the male parent, the toxins of this virus would at some definite period exist in the organs of the female parent after having during the intermediate stage existed in those of the offspring. These toxins bring about an immunity—that is to say, they confer on the tissues powers of phagocytosis or else of secreting bactericidal or antitoxic principles. To sum up, by means of the intermediary within the uterus the maternal cells acquire properties identical with those of the paternal cells. But the maternal organism transmits some of its properties to its descendants. When a new sire comes on the scene, the first one no longer having relations with the mother, and when a new impregnation takes place in the same mother she is able to impart to her new offspring characteristics which have been conveyed to her by the first sire. The phenomena of telegony may be explained in this way.

August 23rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch in Rome.

IN modification of his programme Professor Koch is now in Rome. At the instance of his Excellency the Prime Minister, General Pelloux, who is also (significantly enough, after the bread riots), Minister of the Interior, he was met at the station by the Commendatore Santoliguido and Professor Gozio, both representing the Department of Public Health and both empowered to afford him every facility in the prosecution of his study of malarial fever. Thereafter he had an interview at the Palazzo Braschi with General Pelloux, whence, attended by Professor Gozio, he proceeded in company with his senior assistant, Dr. Pfeiffer, to the Santo Spirito Hospital and began immediately to make the requisite preparations for his researches. He examined many of the patients in the malarial fever wards and on leaving took with him specimens of the blood of the more typical cases. He then repaired to the laboratories connected with the Public Health Department, of which Professor Gozio is director, and with that gentleman's assistance selected the *locale* in which to conduct his experiments. These, it is understood, he will commence immediately, and will prolong his sojourn in Rome for another thirty days at least, or until they are satisfactorily completed.

August 22nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Artificial Respiration.

DR. ANTON BROSCH, in an article published in the *Archiv für Klinische Medicin*, gives an account of thirty-one experiments he has made in order to prove the possibility of the gastric contents being drawn into the lungs during artificial respiration. The greatest quantity of fluid which can be aspirated by artificial respiration amounts to 1210 c.c. The difference between experiments on the dead body and the conditions met with in the living subject is that aspiration of the gastric contents during artificial respiration is more easy in the living subject than in the dead body. The methods of artificial diaphragmatic respiration are the sources of the greatest danger. An experiment made by Dr. Brosch proved that even in the living subject when the stomach is full its contents may be pressed into the pharyngeal cavity by massage and that the cardiac orifice offers but a trifling resistance. An elastic tube introduced into the œsophagus will prevent the contents of the stomach from finding their way into the air passages and Dr. Brosch recommends that this precaution should be taken before artificial respiration is commenced.

Largin.

The *Medicinische Presse* of August 14th contained an interesting report by Dr. Kornfeld on largin, a new remedy for gonorrhœa. It is a greyish-white powder produced by the action of an ammoniacal solution of oxide of silver on an alcoholic solution of the dry product of decomposition of the paranucleoproteids. In a solution even of the strength of 1 in 4000 it kills gonococci in five minutes and is therefore certainly superior to either nitrate of silver or protargol. Dr. Pezzoli, who first made use of it, came to the following conclusions. Largin is of at least the same anti-gonorrhœal value as the other silver-albumin compounds and in its power of killing gonococci it is superior to them; it penetrates more deeply than they do into dead organic substances. These properties show that largin fulfils the most important conditions of an efficacious remedy against gonorrhœa as given by Neisser, killing the gonococci at an early period and entirely without increasing the inflammation of the mucous membrane or injuring the tissues or adding to the pain. Treatment ought to be commenced at an early stage in order to prevent the immigration of the gonococci into the deep parts of the mucous membrane, the connective tissue, and the glands. Largin checks the further proliferation of the gonococci and as it forms no precipitate with albumin it penetrates the tissues, unlike nitrate of silver, which immediately after application produces a film whereby the further penetration of the solution is hindered. Dr. Kornfeld has employed largin in 29 cases of gonorrhœa, in the first group of which, consisting of recent acute anterior urethritis, its success was very marked; the secretion decreased, the gonococci and the filaments disappeared, and the average duration of the treatment was thirty days. In one instance, however, there was an occurrence of slight subacute posterior urethritis during the injections. In the second group, in which the disease had already extended to the posterior part of the urethra and to the urinary bladder, largin caused a decrease but not a complete disappearance of the gonococci.

Digitized by Google

The third group comprised 6 cases of chronic forms of urethritis, some of which presented recent subacute exacerbations. The results showed that largin was superior to the other silver-albumin compounds. A valuable feature of the use of this remedy is the prevention of posterior urethritis.

Insurance against Sickness for Medical Men.

The German section of the Bohemian Medical Chamber is contemplating the formation of an association for providing financial assistance for medical men during illness. Members who are incapacitated by illness will be entitled to 4 gulden (about 8*s.*) daily during the first 140 days and to 3 gulden daily for the next six months. The preliminary circular remarks that the time has gone by when medical men earned enough by practice to make provision for their old age and that they must now be content to make a livelihood. The average income of the majority of medical men in that district is less than £90 a year.

August 22nd.

Obituary.

KAIKHOSRO NASARVANJI BAHADHURJI, M.D. LOND.

INFORMATION has been received of the death of Dr. K. N. Bahadhurji. The deceased, who was a young man at the time of his death, was M.D. of London and a very able physician. Some two years ago he worked in the most devoted way among the plague-stricken population of Bombay and was at the head of the first plague hospital erected in that city. He was an ardent advocate of Indian medical reform and was sent over here by his compatriots in 1896 to plead the cause of reform before the British Medical Association at Carlisle. He embodied his views in a pamphlet called "Medical and Sanitary Reforms in India," concerning which we said in a leading article[1]: "It seems reasonable, on grounds of justice and finance alike, that every effort should be made in the direction of enlarging the uncovenanted medical service, and we do not see why natives should not qualify in hygiene and public health and usefully fill many posts throughout the country." Dr. Bahadhurji was a master of fluent and easy English as well as being generally well read.

THOMAS FRANCIS I'ANSON, M.D. ABERD., L.R.C.P. LOND., M.R.C.S. ENG., J.P.

DR. I'ANSON of Whitehaven, who died at his residence there on August 19th, at the age of seventy-five years, was the oldest medical practitioner in West Cumberland. He was born in London, studied medicine at St. George's Hospital, and became qualified as M.R.C.S. Eng. and L.S.A. in 1846. In the same year he received the appointment of house surgeon to the Whitehaven and West Cumberland Infirmary, and in 1848 published in THE LANCET clinical reports of some of the cases which came under his observation in the fever wards. In due course he became consulting surgeon to the infirmary, an honourable office which he retained until the time of his death. Dr. I'Anson graduated as M.D. at King's College, Aberdeen, in 1848, received the diploma of L.R.C.P. Lond. in 1868, and was made a magistrate for Cumberland in 1888. His practice became very extensive and he held a prominent position among the medical men of the district. He was perpetual vice-president of the Cumberland and Westmorland Branch of the British Medical Association, and when the Association met at Carlisle in 1896 he was president of the Ethical Section and read a paper on the Better Management of a Provincial Infirmary.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board under the Five Years' Regulations in the subjects indicated:—

Part I., Chemistry and Physics:

Acres, George C. Johnstone.
Archer, Henry.
Archibald, Richard James.
Balme, Harold.
Bartlett, Edward Leslie.
Bateman, Ambrose Harold.
Battle, Charles John.
Beadnell, Herbert Owen Marsh.
Bellamy, Henry Francis.
Bent, Percy Claude Vincent.
Best, John Gordon de Graves.
Bishop, Thomas Henry.
Bourdas, John.
Bourns, Frank Grose.
Bradshaw, Gerald Arthur.
Bridges, Roland Harley.
Brown, Robert Dixon.
Bubb, Charles Henry.
Bush, William Henry.
Caton, John Wilfred.
Cheatle, William George.
Cleveland, John Wheeler.
Cole, Percival Pasley.
Corbin, John.
Cordner, Robert H. Lucas.
Couldrey, Thomas Reginald.
Cran, Hugh Rose.
Crozier, George R. Henderson.
Davis, Edward David.
Denyer, Clarence Hamul.
Dixon, Alban.
Dunkerton, Norman Edwin.
Eager, Mervyn.
Edwards, Kenelym Cobham.
Faulks, Edgar.
Featherstone, John Wilfred.
Fennell, Linton Albert.
Fiddian, Arthur Edwin.
Footner, Bertram Maughan.
Garrard, Edward Brown.
Glendining, Bryden.
Hallowes, Arthur.
Halsall, Cuthbert Murray.
Harris, Robert H. T. Penruddocke.
Harvey, Charles Walter Cowell.
Harvey, Frank.
Hawkins, William Lawrence.
Hesse, Harold William.
Hodgson, Ernest Charles.
Ingouville, John George.
Jays, Tom.
Johnson, Edwin Charles.
Jones, Hector.
Jones, Seymour Whitworth.
Lambert-Shea, William Albert.
Lister, Frederick Spencer.
Macphail, Frederick James.
Moon, Archibald Trevor.
Mummery, Stanley Parkes.
Neil, William Herbert.
Nettell, John Patten.
Nicholas, Cecil Francis.
Nicoll, Charles Vere.
Page, John H. Le Bouverie.
Palmer, Harold Thornbury.
Parsons, Edward Daniell.
Price, Ernest Anbrey.
Read, Harold William.
Redwood, Robert V. de Acton.
Reece, Charles Clement.
Roberts, Edmund Arthur.
Rudkin, Gerald Fitzgerald.
Sadler, Vyvyan Kendall.
Salt, Arthur Philip.
Scott, Harold Munro.
Segwin-Strahan, Stuart.
Sexton, Henry William.
Seymour, Charles Gibbons.
Smith, Thomas Morland.
Speechly, Alec John Lincoln.
Spencer, Sandy.
Stranger-Leathes, Hugh Ellis.
Tosswill, Leonard Robert.
Travers, Otho Boyle.
Turnly, John E. L. Alexander.
Walker, Frederick George.
Walker, Henry James Davey.
Walsh, George Delaval.
Welham, George Sydney.
Wickert, Jacob Hodgson.
Wilson, Norman Methven.

Part II., Practical Pharmacology:

Agar, Samuel Annesley.
Anthonisz, Alfred George Henry.
Arch, Arthur James.
Archer, Henry.
Aylen, Ernest Vaughan.
Bailey, William Arthur.
Ball, Charles R. Hamilton.
Bartlett, Ernest John Reeve.
Beane, Robert Leonard.
Beasley, Joseph Howard.
Bedford, Godfrey Henry.
Bellamy, Henry Francis.
Bennett, Henry Stagg.
Bennett, Kenneth Hugh.
Bond, Cecil William.
Brayne, Robert Edward.
Bridges, Roland Harley.
Burpitt, Harry Reginald.
Causton, Hubert Cyril.
Collins, Reginald Thomas.
Compton, Alwyne Theodore.
Crompton, Richard Henry.
Cronkshaw, John Alfred.
Davies, Walter E. Llewelyn.
Davis, Edward David.
Donaldson-Sim, Ernest Alfred.
Downton, Arthur Sydney.
Drabble, Percy Toplis.
Eastmond, Reginald Anthony.
Edwards, Thomas Henry.
Evans, George Jewel.
Ewen, Gerald Sydney.
Fiddian, Arthur Edwin.
Fitz-Henry, Roland S. Wyckham.
Fowler, Trevor Hayman.
Garrard, Edward Brown.
Gauntlett, Owen Binns.
George, Alexander Cosgrave.
Greaves, Herbert Stanley.
Grellet, Harold Rawdon.
Grenfell, Pascoe Beville.
Griffith, William Henry.
Griffiths, Edward Reginald.
Gromitt, John William.
Harris, Robert James.
Harrison, Gerald Woodforde.
Hawkes, Alfred E. Underwood.
Higgins, Hugh Arthur.
Hipwell, Harry.
Hughes, Guy.
Hughes, Edmund Octavius.
Humphrys, George Frederick.
Jackson, Francis Willan.
Jaques, Robert.
Jays, Tom.
Jones, Hector.
Jones, Reginald Lewis.
Jones, William W. Cadwaladr.
Keed, Charles Russel.
Kenderdine, Ernest Henry.
King, William Athol Desmond.
Kirkness, William Ronald.
Lambert-Shea, William Albert.
Lawry, Richard Coger.
Leclezis, George Joseph Alexis.
Lewis, David Thomas.
Lewis, Ivor.
Libby, Harold Samuel.
Lister, Frederick Spencer.
Lower, Charles Antony.
Luxmoore, Evelyn J. Hansler.
McIlroy, William.
Mason, Herbert Alfred.
Melhuish, Herbert M. Herny.
Miller, Arthur Alan.
Mills, Henry.
Morcam, Theophilus William.
Neville, Thomas Crofts.
Pallant, Santiago Luis.
Parbury, Frederick Denis.
Parsons, Wilfred.
Pearson, John Douglas.
Peel, Harold George.
Pierce, Frederick James.
Pierpoint, Harry.
Price, Clifford.
Redwood, Robert V. de Acton.
Row, Charlie Martin.
Sandiland, Digby Sayer.
Scatchard, Thomas.
Scott, Walter Henderson.

Rooth, James Augustus.
Safford, Arthur Hunt.
Topham, Frederick Stocks.

SOCIETY OF APOTHECARIES OF LONDON. — In August the following candidates passed in the subjects indicated:—

Surgery.—H. A. Ahrens, King's College Hospital; M. E. Bennett (Section II.), Royal Free Hospital; E. Fryer, Guy's Hospital; J. E. W. McFall (Sections I. and II.), Liverpool; R. O. Jones and E. MacD. Judge, Guy's Hospital; and O. T. A. Phillips, Cardiff and London Hospital.

Medicine.—F. Atthill (Section II.), Charing-cross Hospital; W. H. I. Bathurst (Section I.), London Hospital; H. R. Cross, Leeds; J. J. Huey, Glasgow; J. Jones, Edinburgh; J. E. W. McFall (Sections I. and II.), Liverpool; R. G. W. Saint-Cedd, Guy's Hospital; W. J. Schuller (Section II.), London Hospital; N. Walmisley, St. Bartholomew's Hospital; J. Welsh, Dublin; and R. Le G. Worsley (Section I.), St. George's Hospital.

Forensic Medicine.—W. H. I. Bathurst, London Hospital; H. R. Cross, Leeds; H. Greenwood, London Hospital; J. J. Huey, Glasgow; J. E. W. McFall, Liverpool; R. G. W. Saint-Cedd, Guy's Hospital; D. C. M. Shaw, Manchester; N. Walmisley, St. Bartholomew's Hospital; J. Welsh, Dublin, and R. Le G. Worsley, St. George's Hospital.

Midwifery.—J. M. Anderson, Aberdeen; E. C. W. Beasley, St. Mary's Hospital; R. Brookes, Westminster Hospital; T. S. Elliot, London Hospital; D. Fletcher, St. Bartholomew's Hospital; H. Greenwood, London Hospital; J. E. Griffith, St. Bartholomew's Hospital; and J. Welsh, Dublin.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—H. A. Ahrens, F. Atthill, M. E. Bennett, E. Fryer, O. T. A. Phillips, and D. C. M. Shaw.

MEDICAL MAGISTRATES. — Mr. William H. Cocker, M.R.C.S. Eng., has been appointed a magistrate for Blackpool.—Mr. Chas. J. Kearney, L.R.C.P. Lond., M.R.C.S. Eng., of South Grafton, New South Wales, has been appointed a magistrate for that colony.

PRESENTATION TO A MEDICAL MAN.—Mr. David Collingwood, M.D. Lond., F.R.C.S. Eng., of Summer-hill, near Sydney, New South Wales, was on June 23rd last entertained at a dinner by his professional and other friends, and presented with a travelling bag, fitted with gold-mounted accessories, on his leaving the district.

THE INFANT LIFE PROTECTION ACT.—The value of the Infant Life Protection Act was tested for the first time in Bristol on August 18th, when a woman was sent to prison for six weeks for having in her custody two children to be nursed and maintained apart from their parents without notice of the fact having been given to the Bristol Board of Guardians.

CHARITABLE BEQUESTS.—The late Mrs. Howard of Blackpool, whose will was recently the subject of some remarkable litigation, left the following local bequests: to the Boys' and Girls' Refuges and the Deaf and Dumb Institute, each £100; to the Blackpool Hospital, £2000; and to the Devonshire Hospital, Buxton, £1000. She also left about £16,000 to religious institutions.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BARRINGTON, F., M.B. Edin., F.R.C.S. Eng., has been appointed an Honorary Surgeon for the Lewisham Hospital for Women and Children, Sydney, New South Wales.

BEESLEY, A. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Baschurch and Middle Sanitary Districts of the Ellesmere Union.

BELDING, D. T., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Mitford and Launditch Rural District, vice M. G. Dundas, resigned.

BONE, BERTRAM MAYHEW, M.B., C.M. Edin., has been appointed Medical Officer by the Towyn and Aberdovey (Merionethshire) Urban District Council, vice F. H. V. Grosholz, deceased.

CLOTHIER, HENRY, M.D. Lond., L.R.C.P., M.R.C.S., has been re-appointed Medical Officer of Health by the Hornsey Urban District Council.

COCKBURN, the Hon. J. A., M.D. Lond., M.R.C.S., has been appointed Agent-General for South Australia, vice the Hon. T. Playford, resigned.

DUNCAN, S. V., L.R.C.P. Lond., M.R.C.S., has been appointed a Public Vaccinator for the Urban and Suburban Districts of Menzies, Western Australia.

ELLIS, R. K., M.B., B.Ch. Oxon., has been appointed Medical Officer for the Lowdham Sanitary District of the Southwell Union.

EVANS, J. JAMESON, M.B., C.M. Edin., M.R.C.S. Eng., has been appointed Honorary Surgeon to the Birmingham and Midland Eye Hospital, vice D. C. Lloyd-Owen, resigned.

FOX, S. C. GUNDRY, M.R.C.S., L.R.C.P. Lond., has been appointed Senior District Surgeon to the Perak Federated Malay States, vice J. L. Welch, deceased.

GILL, J. MACD., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed an Honorary Assistant Physician for the Hospital for Sick Children, Sydney, New South Wales.

GORDON-MUNN, J. G., M.D., C.M., F.R.S.E., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Watford, Barnet, St. Albans, and Chesham County Court Districts, and also to act for the Luton and Leighton Buzzard Districts.

HANDLEY, W. S., M.D. Lond., B.S., F.R.C.S., L.R.C.P., M.R.C.S., has been appointed Dental Anæsthetist and Anæsthetist for the Ophthalmic Department of Guy's Hospital, S.E.

HARDING, R. F., L.R.C.P., L.R.C.S. Irel., has been appointed, *pro tem.*, acting Medical Superintendent for the Hospital for the Insane at Toowoomba, Queensland.

HAWTHORNE, E. S., L.R.C.P. and L.M., L.R.C.S.I. and L.M., has been re-appointed Surgeon to the Etheridge District Hospital, and Medical Officer of Health for the District of Georgetown, Queensland, Australia.

HIRSCHFELD, E., M.D. Strasburg, has been re-appointed an Honorary Medical Officer for the Brisbane Hospital, Queensland.

JONES, MARTIN LLEWELLYN, F.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Lond., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the districts of Merthyr Tydvil, Aberdare, and Pontypridd.

KENNEDY, J. M. P., L.R.C.P., L.R.C.S. Irel., has been appointed a Medical Referee for King's County under the Workmen's Compensation Act, 1897.

KITSON, F. P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Marshwood and Netherbury Sanitary Districts of the Beaminster Union.

LAWSON, G. L. L., M.R.C.P. Edin., M.R.C.S., D.P.H., has been appointed a Public Vaccinator for the Urban and Suburban Districts of Yalgoo, Western Australia.

LEISHMAN, ARCHIBALD, L.R.C.P., L.R.C.S. Edin., L.F.P. & S. Glasg., has been appointed Medical Officer for the Thorncombe District of the Beaminster Union, Dorset.

LETHBRIDGE, C. F., M.R.C.S., has been appointed Officer of Health for the North and West Ridings of Ripon Shire, Victoria, Australia, vice B. J. Adam, resigned.

LONERGAN, T. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for South Australia.

MAIR, L. W. D., M.D. Lond., L.R.C.P., M.R.C.S., D.P.H., has been appointed, *pro tem.*, a Medical Inspector under the Local Government Board.

MARKS, the Hon. C. F., M.D. Irel., L.K.Q.C.P., L.R.C.S., has been re-appointed an Honorary Medical Officer for the Brisbane Hospital, Queensland.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Assistant Lecturer and Demonstrator in Physiology for one year. Salary £120. Applications to the Secretary and Registrar, University College, Cardiff.

UNIVERSITY OF ST. ANDREWS.—Professor of Midwifery.

WESTERN GENERAL DISPENSARY, Stafford-street, Marylebone-road, London.—House Surgeon, unmarried. Salary £60, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

BEVEN.—On August 23rd, at Balham-grove, Balham, S.W., the wife of Octavius Beven, M.D., D.P.H., of a daughter.

BRITTAIN.—On August 16th, at Triangle House, Hatfield, the wife of Percy M. Brittain, Surgeon, of a daughter.

DOVE.—On August 20th, at Parkside, Crouch-end, the wife of Augustus C. Dove, M.D., of a daughter.

PANTIN.—On August 20th, at Albert-terrace, Douglas, Isle of Man, the wife of C. S. Pantin, M.D., F.R.C.S., of a daughter.

RAW.—On August 19th, at Superintendent's House, Mill-road Infirmary, Liverpool, the wife of Nathan Raw, M.D., of a son.

SMITH.—On August 21st, at Dyne-road, Brondesbury, N.W., the wife of J. Anderson Smith, M.D., of a son.

SMITH.—On August 16th, at Orpington, Kent, the wife of A. T. Smith, M.D., of a daughter.

WILLIAMS.—On August 21st, at Brockley, S.E., the wife of Chisholm Williams, F.R.C.S. Eng., of a daughter.

MARRIAGES.

EDMONDSON—ROBSON.—On August 24th, at Egremont Presbyterian Church, by the Rev. James Muir, D.D., Charles Reginald Edmondson, M.B., C.M., of Wavertree, Liverpool, to Ethel, youngest daughter of Stephen Robson, Egremont, Cheshire.

GERRARD—REPTON.—On July 30th, at St. Joseph's Church, Rawul Pindi, Punjaub, India, Major J. J. Gerrard, M.B., Royal Army Medical Corps, to Mabel Kathleen, only daughter of the late Colonel Herbert Mills Repton, Bengal Staff Corps.

HAMLEN-WILLIAMS—RENWICK.—On August 22nd, at All Saints' Church, St. Helier's, Jersey, T. R. Hamlen-Williams, M.R.C.S., L.R.C.P., of Fairfield, Pontypridd, Glam., to Emily Sarah, youngest daughter of the late James Renwick of Bala, North Wales.

HELME—CROFTS.—On August 17th, at the Wesleyan Church, Alderley Edge, by the ex-President of the Conference, Rev. W. L. Watkinson, assisted by Rev. William George and Rev. A. L. Vine, T. Arthur Helme, M.D., M.R.C.P., F.R.S. Edin., of Manchester, son of the late James Helme, of Lancaster, to Florence Jane, elder daughter of the late James Crofts, of Tipton, and Mrs. Crofts, of Alderley Edge.

JACOB—DAY.—On August 18th, at Christ Church, Woburn-square, London, Archibald H. Jacob, L.R.C.S. and L.R.C.P. Ireland, third son of A. H. Jacob, M.D., F.R.C.S.I., Dublin, to Alice Maud, only daughter of Joseph Addison Day, Esq., late of Weston Manor, Corscombe, Dorset.

MAGUIRE—BLISSETT. — At St. Mary's, Bryanston-square, W., on August 14th, Robert Maguire, M.D., F.R.C.P., to Miss Mary Blissett, daughter of the late Thomas Blissett, Esq., of Oxton, Cheshire.

DEATHS.

BLACKMAN.—On August 23rd, at Mostyn, Streatham, Frederick Blackman, M.R.C.S., L.S.A., aged 66 years.

BARROW.—On August 20th, at Guy's Hospital, C. A. G. Barrow, L.R.C.P. Edin., M.R.C.S., of Sutton, Surrey, aged 47.

I'ANSON.—On August 19th, at Whitehaven, Thomas Francis I'Anson, M.D., J.P., aged 73.

SMITH.—On August 10th, at Lodge Park, Freshford, Kilkenny, Ernest Frederic Smith, Major R.A.M.C. retired, of Grove House, Lavenham, Suffolk.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

NE SUTOR ULTRA CREPIDAM.

WE have received from a correspondent a small pamphlet published by a manufacturer of artificial limbs. The articles, if we judge by sundry testimonials, seem very perfect in their way, but there is a passage in the pamphlet to which we must strongly take exception. The passage in question is headed "Observations on Amputations from an Artificial Limb-maker's Point of View," and it goes on to suggest that "the less taken off the better" is not always the best policy. This is no doubt true from the limb-maker's point of view, but he has no right as he does in this pamphlet to say: "When a knee has to be sacrificed the amputation should if possible be performed about four inches above the kneejoint," and still more presumptuous ignorance is shown in the remark, "A portion of an injured hand should never be left, as it is perfectly useless to the patient." It is not the business of an instrument-maker to advise a surgeon how much or how little he shall remove, and such advice is merely a piece of impertinence.

ASSES' MILK.

PHYSICIANS of every age and nationality have commended the milk of the ass as an excellent succedaneum for woman's milk, but according to the following published opinion one eminent authority has come to a precisely opposite conclusion. "The asses' milk which I experimented on," says M. Duclaux, the Director of the Pasteur Institute, "was obtained from one of the droves which are taken round to patients' doors in Paris. It will be seen how little milk so obtained is to be depended on, notwithstanding its enormous price. The specimen which I analysed was very transparent and contained (*a*) substances in suspension: fatty matter, 1·00; casein, 0·99; phosphate of lime, 0·06; (*b*) substances in solution: sugar of milk, 6·54; casein, 0·34; phosphate of lime, 0·10; soluble salts, 0·27. Deducting the sugar, which in milk constitutes two-thirds of the dry residue, it will be seen that in spite of its ten-fold cost this milk is not more than one-third as valuable as cow's milk." Replying to this attack, M. Variot writes to the following effect: "Such a condemnation cannot be final but must admit of an appeal, being founded on one analysis only, which, with regard to butter and casein, is in conflict with the analyses of Féry and Gautrelet. And, moreover, if asses' milk is more easily assimilated than cows' milk by certain debilitated nurslings it is precisely on account of its lightness and poverty in casein. The excess of protein substances in cows' milk, which causes American physicians so much anxiety, is not to be dreaded in asses' milk. M. Duclaux may say, if he pleases, that as a cheese producer asses' milk is valueless by reason of its lack of casein, but the fact, nevertheless, remains that for puny children deprived of the breast it is the very best substitute for their natural food." Doubtless this view will obtain most suffrages. Such, at least, is the opinion of an anonymous commentator, who exclaims, "We are on the side of M. Variot and clinical experience against M. Duclaux and chemistry. Yes, asses' milk is unquestionably the proper succedaneum for maternal milk and that precisely because, like woman's milk, it is poor in casein."

A COURTEOUS SUGGESTION.

THE *Daily Mail* of August 24th publishes the following letter:—

"CHEMISTS AND DOCTORS.

"A subject that affects the interest of the public to a momentous extent is that of dispensing by doctors. At present it can be used in the hands of the unscrupulous to smother crime.

"There is not the division of labour between the doctor and the chemist there should be. The doctor should prescribe and the chemist dispense, and there ought to be no departure from this rule. At present, dispensing by the chemist is the exception, save in the West-end of London and fashionable resorts.

"In 1868 the Pharmacy Act came into force, wherein it decreed that before a chemist be permitted to dispense and sell scheduled poisons he must prove himself capable by passing a very stringent and searching examination in chemistry, pharmacy, materia medica, and dispensing. Since then 90 per cent. of the chemists have passed these examinations, yet the bulk of dispensing is done by the doctors, who have but a smattering of the art.

"The gravest point is this, that through inadvertence or by design the medical man may send medicine improperly dispensed, or containing some poisonous drug by which his patient becomes very ill or dies. In the one case he can explain his error away; but in the latter he can sign the death certificate and for ever hush up the true cause of decease. "JOSEPHUS."

We call this an infamous insinuation. Of course it is possible that a medical man may poison his patient either "through inadvertence or design"—anything is possible. For all we know "Josephus" may be a criminal of the deepest dye, but it is more probable that he is a struggling dispensing chemist.

NEWS FROM FRANCE.

(NOT FROM OUR CORRESPONDENTS.)

WE confess to being lost in doubt whether the articles from the *Journal de Médecine de Paris* translated extracts from which we subjoin are intended as examples of *esprit* or of "wut." They cannot be serious. Is it that the writers, after visiting the northern capital, have sought to combine the two—to serve up a s rt of humorous *gâchis*, as it were a haggis flavoured with absinthe?

"OUR DOYEN IN LONDON.

"The above headline does not refer to the *doyen* of the Faculty of Medicine, but to the gentleman who hails from Reims. The lay press informs us that M. Doyen, that Napoleon of surgery, was summoned to London in order to perform several operations of the gravest possible description. The illustrious surgeon was presented to the Princess of Wales and exhibited his operative procedure with the utmost success before numerous English surgeons and also before the students of St. Mary's Hospital. The patients he operated on are all progressing most favourably. The Queen of England sent to ask M. Doyen if he was willing to accept a post as Her Majesty's Surgeon in Ordinary with a salary of 10,000 'guignées' per annum; but our compatriot refused, being unwilling to deprive France of his services. Upwards of two-thousand English medical men made a point of accompanying M. Doyen when he left. He promised to take part in the Congress of the British Association at Edinburgh, and the moment the news became known the hotel tariff in the Scottish capital was trebled."

The following announcement is taken from the same source. Its humorous character is not so obvious:—

"*Necrology.*—Lord Playfair, Commander of the Legion of Honour, sometime Professor of Chemistry at Manchester, at Edinburgh, and at Saint-Andrews, one of the most distinguished of hygienists, has just succumbed at the age of 79 years. Formerly vice-president of the House of Commons, formerly Minister of Public Instruction in one of the Gladstone ministries, Lord Playfair was raised to the peerage in 1892. But this accoucheur was above all celebrated through the misadventure which befel him two years ago when he was condemned to pay a quarter of a million francs damages for having unduly disclosed the fact that one of his patients had had a miscarriage."

THE BONE-SETTER AGAIN.

MR. A. T. SHEPHERD, deputy coroner, held an inquest at Gateshead on August 18th to inquire into the circumstances of the death of Isabella Keenan, aged thirteen years. It appeared in evidence that she had been ill for three weeks and was attended by Dr. Arthur Green. Then she was taken to a bone-setter, but she got worse. Dr. Green was sent for again on a Friday but the girl died on the following Wednesday. Clayton, the bone-setter, said that he found that the muscles of the right leg were contracting. He "eased them down" and put on a bandage. Her back had been blistered. Dr. Arthur Green said that when he first saw the girl she had severe bruising of the muscles of the back, and had been blistered over the loins. When next he saw her she had a large gangrenous patch upon the back and was crying; she had pneumonia as well. He considered the gangrene was due to the over-tight bandaging. The coroner said that Clayton had been negligent, though he did not think criminally negligent. Probably if Dr. Green had had charge of the case all through the poor girl would not have died. The jury considered that Clayton had been negligent and ought to have called in a medical man. The death was due to the causes enumerated in the medical evidence. We make no comment upon this case, for it is of no use. This is a free country and practices of this description are quite legal.

THE TITLE OF "DR."

To the Editors of THE LANCET.

SIRS,—I am a Bachelor of Medicine of the University of Cambridge, also a Bachelor of Surgery and Bachelor of Arts. Am I right in having inscribed upon my doorplate and visiting cards simply "Dr. X"? This has been called in question by some of my fellow practitioners, who contend that as I am only a Bachelor of Medicine I have no right to style myself "Dr." I know it is the custom of Cambridge and Oxford Bachelors of Medicine to style themselves "Dr.," but I should be very pleased to have your authority to point to, which would, of course, end the matter at once. I am, Sirs, yours faithfully,

August 22nd, 1898. X.

*** It is usual for a Bachelor of Medicine to style himself "Dr." and we have not before heard any objection to the custom from his professional brethren. Our correspondent is referred to THE LANCET of August 17th, 1895, where the subject is discussed at length in a leading article.—ED. L.

THE LATE ARTHUR JEFFARES BARLOW.

IT has been decided to keep the appeal on behalf of the widow of the late Mr. Arthur Barlow open for a short time longer. Mr. R. H. Capper, of Buckholt, Battle, Sussex, who will receive subscriptions, asks us to acknowledge the receipt of the following contributions:—Far away, £5 5*s.*; Mr. Snook, Weymouth, per Dr. Henry, £2.

PROSECUTION OF PECULIAR PEOPLE.

ON August 24th a carman and his wife, named Cook, were committed from the Lambeth Police-court for trial on a charge of the manslaughter of their child. The prisoners are Peculiar People and the child had been ill for six weeks with no medical attendance. An "elder" had, however, anointed the child and prayed over it. Medical evidence showed that the death was due to broncho-pneumonia.

A HERBALIST IN TROUBLE.

AT Norwich, on August 23rd, Mr. Samuel Matthews, a former member of the town council of the city, was fined £1 by the magistrates for unlawfully using the title of "Surgeon." On the following day Mr. Matthews, who was a medical herbalist, was fined £20 in the county-court at the suit of the Society of Apothecaries of London for illegally acting as an apothecary. Mr. Matthews's counsel called the prosecution "persecution," but was informed by his honour Judge Willis in giving judgment that he could see no persecution in the matter; it was most important that persons who undertook the care of other people's health should be duly qualified. We quite agree, but unfortunately the law does not. A summons for illegally using the title of "Doctor" was dismissed.

"ETHERION."

THE New York correspondent of the *Standard* announces the discovery by Mr. Charles Brush of an exceedingly attenuated gas to which has been given the name of "etherion." It would appear to invade all interstellar space and may prove to be the "matter" or "ether" by the vibrations of which alone can many physical phenomena be explained. It occurs in the atmosphere and its density is one-thousandth of that of hydrogen. If this announcement—which was made at a meeting of the American Association of Science—be correct we would appear to be approaching the discovery, or even isolation, of Crookes's "protyle," the primordial element.

A. J. G. entered into a bond and he must keep the terms thereof whether the other party to the agreement be a layman or not. We quite agree with him that it is inadvisable for a medical man to become a servant of these lay associations—we have said so over and over again—but we cannot advise that an agreement once entered into should not be kept.

Public Health is requested to send his name and address—of course not for publication—and also the name and date of the newspaper wherein the report appeared. We will then make a note of the matter if it seems to us that to do so will be useful.

Emigrant.—The regulations governing medical practice in America vary in the different States. Full information will be found in THE LANCET of Sept. 12th, 1896, page 769, and also in our issue o Oct. 3rd of the same year, page 969.

M. G. Y. E.—We do not as a rule publish letters which have already appeared elsewhere.

Percy.—We do not recommend treatment.

F.R.C.S. must verify his references.

H. S. should consult a lawyer.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.) St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

WEDNESDAY (31st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (1st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex, (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

FRIDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (3rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

During the week marked copies of the following newspapers have been received: *Birmingham Gazette, Nottingham Express, North Herts Journal, Luton Reporter, Walsall Observer, Torquay Times, Wilts Standard, Ilfracombe Chronicle, Times of India, Pioneer Mail, Warwick Advertiser, Architect, Citizen, Scotsman, Builder, Liverpool Daily Post, High Peak News, Driffield Observer, Leeds Mercury, Wigan Examiner, Derby Times, Ampthill News, Harrogate Advertiser, Bristol Mercury, South Wales Daily News, Eastern Morning News, Croydon Guardian, Bridgwater Independent, Yorkshire Post, Chester Chronicle, East Essex Times, Lynn News, Lancashire Express, Manchester Guardian, Western Morning News, Newcastle Journal, Cheltenham Mercury, Hereford Times, Lancaster Guardian, North Middlesex Chronicle, Worcestershire Echo, Sanitary Record, Mining Journal, St. Bartholomew's Hospital Journal, City Press, Reading Mercury, Hertfordshire Mercury, Observer and Chronicle (Bournemouth), Local Government Chronicle, Guy's Hospital Gazette, Surrey Advertiser, Redditch Indicator, Local Government Journal, Australasian Medical Gazette, Forres Gazette, Falkirk Herald, Brecon County Times, Buckingham Express, Freeman, Exmouth Journal, Seaford Journal, Market Rasen Mail, School Guardian, Aberystwyth Observer, Cromer Post, Grantham Journal, Harwich Chronicle, Kendal County News, Dover Express, Andover Advertiser, Loughborough Monitor, Western Daily Press, &c., &c.*

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 3, 1898.

ADDRESS TO STUDENTS.

IN the Students' Number it has always been our custom to offer a few words of advice to those who are about to enter on their medical studies and this we now proceed to do.

In accordance with the present system of education for boys destined to enter the medical profession, some of the preliminary subjects — chemistry, physics, and biology—have already been dispensed with before leaving school, and in the eye of the law those so grounded in the science of medicine are "medical students" for some little time before entering a hospital. But on actually joining a hospital they will be commencing a new stage of life, and it is at this point that counsel may prove of value. Many of our profession, now advanced in life, will doubtless look back with gratitude to the words uttered by some eminent physician or surgeon, long since dead, which have never been forgotten and which produced an effect on them influencing their whole medical career and more than possibly never passing off. The annual gathering at medical schools for the purpose of hearing such an address has been discontinued by some of the schools, while the habit is carefully preserved by others. There is much to be said for it. The first-year students feel that they have had a definite introduction to their fellows and to their future teachers; parents depart content that they have seen the staff and the school and we believe that, as a rule, the assembly disperses with a feeling of satisfaction at having been participators in an old custom conceived in a pleasant spirit of friendly welcome and carried out as a rule effectually. For the occasion need not reduce the lecturers to triteness or bald preaching, as their range of subjects is practically limitless, their audience not being confined to medical students.

Our audience, however, this week is by design confined to medical students, so that we shall make no apology for going over ground which we have previously traversed as we shall go over it in new company. The first word we have to say is one which has been said constantly and all our readers will hear it from the lips of their teachers for the next five years—or longer. The value of practical work is incalculable. Reading should supplement it and never be substituted for it. Anatomy can only be learned in the dissecting-room and not from books and plates; diseases, medical and surgical, can only be thoroughly studied by the bedside; and a knowledge of pathology and of the newly introduced science, bacteriology, can be only attained in the post-mortem room and in the laboratory. Such instances can be multiplied to any extent, but we need only refer to one development of the tendency to go to text-books rather than reality for information to show how unfortunate such a spirit is to its possessor. It is the man of text-books who regards the patients as so many cases rather than as individuals. He is concerned to make their symptoms fit his books rather than to make his medical knowledge and his knowledge of life explain their symptoms to him. Such a habit is apt to grow and to be carried subsequently into private practice, proving a fatal mistake for the young practitioner.

Not that we want to decry the value of text-books, but just to point out that they are to be employed as means only in whatever way will best assist practical work. The use that the student will be able to make of text-books will vary entirely with his order of mind. To one man the small elementary book may be well-nigh sufficient reading. He will be able to use it as the skeleton of his knowledge and will endow it with tissues and life from his personal observation, by practical courses in his school, by clinical work in the wards, and by thoughtful attendance at lectures. This is the student into whose work books do not largely enter. To other men the orderly arrangement of knowledge by their masters will appeal more strongly and they will be tempted to substitute books for practical work. And inasmuch as it is easy to examine fairly and thoroughly upon book work, while it is difficult to lay down proper standards and to discover adequate tests for the appraisement of practical work the result of examinations must more or less depend upon the ability of the student to answer somewhat in text-book language questions framed somewhat upon text-book lines. So that the man who knows his book work only may now and again pass an examination where his more practical and really better instructed comrade may fail. But this fact is no argument for the wrong use of text-books. Practical work at the laboratory bench, in the dissecting room, and in the wards is the essence of the medical student's training, and we beg all our readers to remember this.

We now come to another side of the medical student's life. During his school or college days he may have taken a prominent part in games; he may have been a shining light in cricket, football, or athletic sports. On leaving school or college he not unfrequently gives up such sports entirely. This may be due to various causes, either to enthusiasm for his new studies, or to a feeling that the time has come to put away childish things, or because he has the bad luck to make the acquaintance of elder students who are using their freedom from disciplinary restraints in smoking too much and playing certain indoor games. The young lad fresh from school may think it is "like a medical student" to live such a life and may quickly fall into similar ways and give up all forms of out-door exercise. But whatever may be the cause that he abstains from athletic pursuits, and equally whether that cause is worthy or unworthy, such abstention is a great mistake, and will probably be everlastingly regretted. Fortunately the idea that a medical student is necessarily a rowdy, undisciplined youth is becoming obsolete, and those who have close acquaintance with medical schools will confirm the statement that the idle, dissolute man is a rarity, nor, thanks to the watchful care exercised by the deans and wardens, does he long dishonour his school by his presence. The puerile desire to disturb the teachers has practically died out; the lecturer on chemistry conducts his demonstrations without fear of explosions and the botanical specimens are no

Digitized by Google

longer hopelessly mixed. All these things show the signs of the times and indicate that the student who leaves off athletics to indulge in dissipation would be comparatively lonely as well as a person of no consideration among his fellows. But they also prove the existence of new temptations to a lad to cease to take the exercise which his young bones and lusty blood call for—the temptations of over-assiduity. Most medical men will be able to recall instances in which an athlete has forsaken the field, river, or running-path for his books, laboratory, and other sedentary occupations, and whose health has waned until he has become dyspeptic or falls a prey to some serious illness. It is usually a fatal error for anyone who has been accustomed to an active life to give up all forms of regular exercise. Still worse is it when the lassitude is due to indulgence in tobacco and late hours. At all the medical schools are various clubs for cricket, football, and rowing. We would strongly advise every new student to attach himself to one or more of these associations. If he has never been accustomed to such exercises previously, there is all the more reason why he should commence when extra study and the atmosphere of the lecture-room, laboratory and wards will make a call upon his strength and constitution. It is a recognised fact that a man can excel both in his studies and in athletic pursuits, and to encourage medical students to keep up their athletic attainments, numerous challenge trophies have gradually come into existence. There is another form of physical culture (to employ a term which has lately come to the fore) which is sadly neglected in the United Kingdom. In Germany the gymnasium is one of the most prominent institutions amongst all classes of the community, especially students. With us, however, after school life the gymnasium is a wholly unknown institution. And yet what can be more beneficial than daily exercise in some form of gymnastics? Few, if any, medical schools can boast of gymnasiums, but we believe their general establishment would prove a great advantage. An elaborate set of apparatus is not necessary, but if a room could be set aside for the purpose the needful bars, rings, and other accessories could be gradually added.

And now we must add a word of caution, said countless times before but which nevertheless must be said again. Any good thing may be abused and the tendency to neglect studies for sports cannot be denied to be as strong in some as the inclination to discontinue athletics is in others. That physical culture and mental education are perfectly compatible is proved every day, and the proper practice of athletics strengthens the mental faculties. Our desire is to warn men from becoming one-sided. We have no wish that the county cricket and football teams or the champions on the cinder paths of the London Athletic Club should be largely recruited from the medical schools, but if embryo physicians and surgeons would pay more attention to the study of physical improvement as exemplified by gymnastics and manly sports we believe it would be to the benefit of the community in general. A greatly improved tone has been apparent amongst the boys of public schools since "games" have been made compulsory and loafing sternly discountenanced, and in particular since (as has been wisely ordained by certain headmasters) those boys possessed of "doctor's certificates" have been made to appear at call-over at a spot three or four miles away from the school buildings. The continuance of some form of physical exercise after school-life is not sufficiently insisted on by medical men. Swedish Drill or some other similar exercises do an incalculable amount of good, and it would greatly benefit the individual if such practices were not entirely thrown on one side on leaving school. Ten minutes or a quarter of an hour earlier rising is no real hardship to anyone—though in the morning we are not all stern enough with ourselves to believe that this is so—and that time spent in one of the numerous forms of domestic gymnastics now introduced would be sufficient to preserve and in some cases to increase the physical development attained whilst under scholastic control.

All who follow the medical profession must be students for ever—students as much in the fifth year of their curriculum as in the first; students as much at the end of their life's work as when confronted with their earliest patients. From every case for the real physician and the real surgeon a lesson has to be drawn: perhaps a new point arises, perhaps only a point confirmatory of what has been previously familiar; but in either instance something worth knowing has to be learned. And this is at once the great difference between book-learning and the learning which is the outcome of practical observation. To a certain extent the need for book-learning may be finite, and to a great extent this need is modified by the idiosyncrasy of the individual. But no man from the moment that he places his foot on the lowest rung of the ladder of medicine can dispense with observation or the results of observation. This need is never finite. A certain quickness in the detection of, and a certain facility in the reading of, the meaning of symptoms and signs and the influence of family history and environment are given to some in an extraordinary degree; but most certainly, should any man, being gifted in this fortunate manner, presume to think lightly of, perhaps to forego, some of the routine of observation, in the end he will be the worse off for his talents. He will make errors, and will speedily know himself, and others will as speedily know him, to be a superficial adviser. For book-learning there is a substitute—practical work; for practical work there is no substitute.

The gist of our sermon this year to students, therefore, is that they should cultivate their habits of observation by wringing from their practical work every scrap of advantage that is possible; that they should read the best text-books as supplements to their practical work; and that they should resolve to give up a certain portion of their time to the due practice of athletics—that is, to the preservation of their healths. A weakly individual may exhibit good mental development for a short time; but whilst high physical powers judiciously maintained tend to prolong life and to protect their owner from many of the minor ailments to which weaker constitutions are liable, they at the same time increase the capacity of the brain. Moreover, the regular pursuit of some form of athletics greatly raises the moral tone of a young man. The individual who wishes to improve his physical powers must cultivate habits of temperance and self-control. Evil habits, which the self-indulgent and slovenly man so easily falls a prey to, are obnoxious to the athletic and healthy-bodied, for late

Digitized by Google

hours and their numerous evil consequences will be perforce eschewed. Let the medical student learn to live that he may be able to draw from his personal experience when he is advising his patients what are the best ways of keeping well.

A TEACHING UNIVERSITY FOR LONDON: A HISTORICAL SKETCH.

IN 1864 suggestions for adding teaching functions to the University of London were made by Mr. BOMPAS and Dr. SANSOM, but were summarily rejected by the Senate. Dr. PYE-SMITH'S resolutions in 1878 met with a similar fate, as did also those adopted by Convocation in 1881 and 1882. The first important outside movement directed to this object began in 1884. Fourteen years have therefore elapsed between the starting of this movement for promoting a teaching university for London and the appointment of a Statutory Commission to arrange the details by which the university should be guided in carrying out the duties laid down in the Bill which has now passed through both Houses of Parliament. In association with the movement for promoting a teaching university, either as a new institution or by reconstituting the present University, the medical profession in London has been most anxious to secure for London medical students a degree on similar terms to those which are granted to the students in the Scotch and provincial universities.

The dissatisfaction which most educational experts in London felt with the attitude of the University of London towards higher education in London led in November, 1884, to the formation of an association for promoting the establishment of a teaching university for London under the presidency of Lord REAY and the vice-presidency of Sir GEORGE YOUNG, and the association immediately entered on an active propaganda in support of its principles and objects. These were defined by the association as follows:—

1. The organisation of university teaching in and for London, in the form of a teaching university, with faculties in arts, science, medicine, and laws. 2. The association of university examination with university teaching, and the direction of both by the same authority. 3. The conferring of a substantive voice in the government of the university upon those engaged in the work of university teaching and examination. 4. Existing institutions in London of university rank not to be abolished or ignored, but to be taken as the basis or component parts of the University, and either partially or completely incorporated with the minimum of internal change. 5. An alliance to be established between the University and the Professional Corporations, the Council of Legal Education as representing the Inns of Court, and the Royal Colleges of Physicians of London and Surgeons of England.

A sub-committee was appointed to draw up a scheme in accordance with these objects and it attracted much attention and support from the teachers of London. If this scheme erred it was in the direction of trying to bring together too many of the heterogeneous educational bodies existing in London. On Lord REAY being appointed to the Governor-Generalship of Bombay the late Mr. JOHN MARSHALL accepted the presidency of the association. This movement naturally alarmed the Senate and Convocation of the University of London, as it was directly aimed to fill up the gap in London education, which their institution had been formed to occupy, and which they had deliberately declined in order to become an Imperial examining board instead of a local university. Many of the graduates, however, were in favour of reforming the University on the lines laid down by the association, so on Jan. 6th, 1885, a special committee of forty members was appointed to consider its proposals. On Feb. 24th they reported to Convocation that the objects of the association would, if carried into effect by the University, add to its usefulness and importance. This report was carried by a large and influential majority and the committee was re-appointed. A scheme embodying these proposals was drafted by a sub-committee with Lord Justice FRY as chairman, but after a prolonged discussion on July 28th and Nov. 3rd of the same year was rejected by 43 votes in favour of an amendment of Mr. (now Sir) PHILIP MAGNUS to refer back the scheme for consideration and to increase the number of the special committee by 20 names. Most of the members of the special committee at once resigned. Mr. MAGNUS'S scheme, which varied but little in its general plan from that of Lord Justice FRY, was brought before Convocation of Dec. 8th, 1885, and was referred to a special committee of twenty-five members to work out the details and lay them before Convocation.

Meanwhile the question of degrees for London medical students had been brought before the profession by the late Dr. WALTER MOXON in a most lucid and powerful article in our columns on July 25th, 1885, entitled "The Demand for Equitable Graduation in the South of England, being a Study of an Unfulfilled Duty of the Royal Colleges of Physicians and Surgeons." He pointed out that these Colleges, if empowered to grant medical degrees, would at once constitute a teaching university in London and be the nucleus or centre of growth of a more general teaching university. A memorial in favour of this movement was presented to these Royal Colleges bearing the signatures of over 600 teachers, practitioners, and students of medicine. A committee of delegates of the two Colleges had already presented a report, which was fully considered in October, 1885, and a resolution moved by Dr. (now Sir) SAMUEL WILKS was adopted in the following terms: "That it is desirable that persons examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly, and found duly qualified, either by the ordinary or an additional qualification, should have a degree in medicine and surgery conferred on them." It is interesting to know that Dr. FINCHAM, Dr. S. O. HABERSHON, Dr. C. WEST, Dr. (now Sir) WILLIAM GOWERS, Dr. (now Sir) W. H. BROADBENT, Dr. SANSOM, Dr. BARNES, Dr. WILSON FOX, Dr. NORMAN MOORE, Dr. MOXON, Sir ANDREW CLARK, Sir HENRY PITMAN, and Sir WILLIAM JENNER, all spoke in favour of the movement. This preliminary report, having been referred to the Councils of the Royal Colleges and reported on, was further considered by the committee of delegates at very frequent meetings and they again reported in December, 1886, in favour of the granting of a degree in medicine and surgery to London medical students by the Royal Colleges and that an application for this purpose should be made to the Crown. A carefully drawn up statement giving the reasons for this step accompanied

Digitized by Google

the report of the delegates. This final report came before both Colleges on Dec. 16th, 1886, after a most interesting discussion at the Royal College of Physicians of London as to whether the degree should be conferred by the Colleges acting by themselves alone or by some university outside the Colleges but on which they could be represented. This obviously was intended to include either a reformed London University or such a university as was contemplated by the Teaching University Association. On the 23rd an amendment taking the latter view was defeated by a large majority and the two Colleges were now definitely pledged to go on with their own scheme.

On June 29th, 1886, Mr. MAGNUS'S scheme, which differed but little in its essentials from that of Lord Justice FRY, was passed by Convocation but was no more acceptable to the Senate than the former one had been. The year 1887 was practically spent in conferences between the various bodies interested and three new schemes were ultimately brought forward, one by the University of London as representing the views of the Senate; a second by the Royal College of Physicians of London and the Royal College of Surgeons of England; and a third by University College and King's College, London. All these applications were put in for hearing before the Privy Council before January 16th, 1888, but in consequence of a multiplicity of petitions for and against them, and of the great importance of the question, Her Majesty's Government advised the appointment of a Royal Commission. In May, 1888, the Commission was formed and held its first meeting on June 2nd. Lord SELBORNE was the chairman, and the other members were Sir JAMES HANNEN, Mr. BRODRICK, warden of Merton College, Oxford, Sir WILLIAM THOMSON (now Lord Kelvin), Professor (now Sir GEORGE) STOKES, Vice-Chancellor BALL, and Dr. WELLDON, with Mr. J. L. GODDARD as secretary. The Warden of Merton College resigned after the first sitting on a question of procedure as to the limitation of the proposed evidence. After hearing most voluminous evidence the Commissioners issued their report on April 29th, 1889, in which the petition of the Royal Colleges to grant degrees in medicine and surgery was unanimously rejected. A reconstitution of the University of London mainly on the lines of the scheme of Lord Justice FRY was unanimously recommended to be tried, but in a separate note the members more immediately connected with education—viz., Sir WILLIAM THOMSON, Professor STOKES, and Dr. WELLDON—declared their preference for the establishment of a new teaching university in London without interfering with the work so ably done by the existing institution, although they would permit the existing institution to undertake the new duties if it could, which they doubted. If a proper scheme in full accord with the recommendations of the Commissioners were forthcoming from the University of London the petition of University and King's Colleges to be constituted into a university was not to be granted. Conferences between the various bodies interested and the Senate and between the Senate and Convocation as to the modifications required to meet the views of the Commission led to no result, so Lord CRANBROOK, as Lord President of the Privy Council, wrote to the University of London at the end of 1890 asking their intentions with regard to a new Charter. After many futile attempts a finally revised scheme "was drawn up" by the Senate and submitted to Convocation in 1891. This was too complicated to receive much support and was rejected by a large majority.

Two years of conferences had led to no result and Lord CRANBROOK at once gave notice that he would fix an early date for a meeting of a Committee of the Privy Council to take into consideration the petition of University and King's Colleges "to be a university in and for the London district, having power to grant degrees in the Faculties of Arts, Science, and Medicine, with power to add other faculties." The Lords of the Privy Council passed the Draft Charter of this new University leaving the two Royal Colleges to determine whether they would accept the representation offered to them in the new University. This was declined, but the alternative representation of the ten medical schools was accepted, and so they became, with University and King's Colleges, constituent colleges in the University. The University was to be called the Albert University, but afterwards, when the Joint Grand Committee of Gresham College had given their full support to the scheme, the name was by consent changed to that of "Gresham." The draft charter had to be laid on the table of both Houses of Parliament for thirty days. During the Parliamentary recess a most determined opposition was started by the authorities of the Victoria University and the provincial medical colleges, supported by many members of the Senate and Convocation of the University of London, by Bedford College, the Birkbeck Institute and similar bodies, and the University Extension Society. Many London professors, especially in science, urged the formation of a professorial university in opposition to a federated one. Parliament assembled in February, 1892, and on March 3rd Lord SALISBURY received a deputation representing these interests at which Vice-Principal RENDALL and Mr. CHAMBERLAIN were the principal speakers. On March 9th the Draft Charter was remitted by Mr. BALFOUR for reconsideration and on April 25th a new Royal Commission was appointed "to consider and if they think fit alter and amend the proposed Charter remitted in compliance with an address of the House of Commons, so as to form and report to us a scheme for the establishment under Charter of an efficient teaching university of London." The members of the new Commission were Earl COWPER (chairman), Lord REAY, Bishop BARRY, Lord PLAYFAIR, Vice-Chancellor RENDALL, Professor RAMSAY, Professor SIDGWICK, Canon BROWNE, Mr. ANSTIE, Q.C., Mr. R. C. PALMER, Sir W. S. SAVORY, Sir G. M. HUMPHRY, and Professor BURDON-SANDERSON, a well selected group of men representing practically all the interests involved in the solution of the question.

The sittings began on May 21st, 1892, and after hearing most lengthy, and in many respects contradictory, evidence, as well as a recapitulation of that put before Lord SELBORNE'S Commission, the new or COWPER Commission were not able to report before January, 1894. The chief recommendations then were that there should be one university with teaching functions confined to London and that the existing university should be reconstructed so as to carry on this work without interfering with its present duties, and that University College, King's College, Bedford College, the Royal College of Science, the City and Guilds of

Digitized by Google

London Institute, certain theological colleges and colleges of music, and the London medical schools should be at once admitted as schools or colleges in the University. The students were to be divided into those attached to those institutions (internal or collegiate students) and those unattached (external or non-collegiate students). The examinations for the internal students were to be arranged by an Academic Council of the members, and those for the external students by a board specially appointed for that purpose. The final examination for the degrees in either were to be the same or to represent the same standard of knowledge, and "identical, so far as identity is consistent with the educational interests of both classes of students." The governing body was to be a Senate composed of the Chancellor and 65 other members. It was also proposed that these recommendations should be effected not by Charter, but by legislative authority and by the appointment of a Commission with statutory powers. These recommendations were accepted by the Royal Colleges and by University College and King's College after some modifications in favour of the latter. Deputations in support of and in opposition to the scheme were received by Lord ROSEBERY as Prime Minister and were told that the Government would "consult very largely the vote of Convocation, whenever it is taken." On Jan. 22nd, 1895, a meeting of Convocation took place, when 206 voted in favour of the scheme and 174 against. On May 14th, at the next meeting, Mr. BOMPAS endeavoured to get the resolutions which had been passed at the last meeting rescinded, but he was defeated by 238 votes against 116. As if to show the futility of consulting the graduates Mr. NAPIER, LL.D., a marked opponent of the scheme, was elected a Fellow of the Senate at the same meeting by 1231 votes, whilst only 738 graduates supported Mr. COZENS-HARDY, one of its most prominent and influential advocates.

On May 9th, 1895, Lord PLAYFAIR introduced a Bill in the House of Lords to carry out the recommendations of the Cowper Commission. The Bill was a very short one and the operative clause was as follows:—

1. The Commissioners shall make statutes and ordinances for the University of London in general accordance with the scheme of the report hereinbefore referred to, but subject to any modifications which may appear to them expedient after considering any representations made to them by the Senate or Convocation of the University of London or by any other body or persons affected.

2. In framing such statutes and ordinances the Commissioners shall see that provision is made for securing adequately the interests of non-collegiate students.

3. All such statutes and ordinances shall be laid forthwith before both Houses of Parliament and shall come into operation on the expiration of forty days after they have been so laid, and shall have effect as if enacted by this Act, but shall be subject to alteration in the manner provided by such statutes and ordinances.

The Bill passed its first reading, but its further progress was stopped by the resignation of the late Government. On the accession to office of the present Ministry an influential deputation waited on Nov. 28th, 1895, on the Duke of DEVONSHIRE, as Lord President of the Privy Council, asking him to introduce a similar Bill, but with a right of appeal to the Privy Council added. The deputation met with little encouragement and Sir JOHN LUBBOCK in his election address adopted the strange position that every graduate should be able to exercise the right of veto even by a proxy vote and without a personal attendance at Convocation, so that the prospects of the Bill at the end of 1895 were far from hopeful. The opposition of the graduates was further shown by the rejection of Sir JOSEPH LISTER (now Lord LISTER) as a Fellow in favour of the late Mr. WALTER RIVINGTON in June, 1896. Another amended Bill was introduced in the House of Lords, and it passed but was withdrawn in the House of Commons. Other tentative measures were tried in 1897. Some important points not in the former Bills were now introduced by way of compromise, and these satisfied a large section of Convocation which had formerly been actively hostile, although many graduates under the leading of Mr. FLETCHER MOULTON still continued a strenuous opposition. The Bill was, however, again introduced in the House of Lords by the Lord President on Feb. 21st, 1898, when it passed through the various stages without material alteration. It was then introduced in the House of Commons and passed the second reading on June 15th, when it was at once referred to the Standing Committee on Law. It was returned from this body practically unaltered and, although many obstructive amendments—formerly defeated—were again urged, it passed successfully through the Committee stage in July and received the Queen's assent on August 12th.

Sir JOHN GORST is much to be commended for the firm but courteous manner in which he piloted the Bill through the Lower House and the solution of the question will do the Government great credit. The Statutory Commission is composed of Lord DAVEY, the Bishop of LONDON, Sir WILLIAM ROBERTS, M.D., Sir OWEN ROBERTS, Professor JEBB, Professor MICHAEL FOSTER, M.D., and Mr. EDWARD HENRY BUSK, LL.B., and we hope that they will begin their important and laborious work as speedily as possible. Mr. T. BAILEY SAUNDERS has been appointed secretary to the Commission.

POST-GRADUATE INSTRUCTION ABROAD.

MEDICAL study is only nominally complete when a licence to practise is obtained, and all qualified men will acknowledge the importance of keeping themselves well informed in the various improvements in diagnosis and practice which are from time to time introduced. The opportunities afforded by post-graduate courses in this country are periodically referred to in the columns of THE LANCET; and with the object of treating the subject as fully as possible a short series of articles is now published, showing what has been and is being done in this direction at the great continental schools. In this connexion it is not necessary to remind our readers that Vienna, for instance, has for many years been a favourite place of study for medical men desirous of completing their education after having gained their diplomas, and the institution of special courses there, to be carried on in the vacation months, will be a further inducement to resort to this famous centre of medical learning.

FRANCE.

There is not in France any special institution corresponding exactly to the post-graduate schools of some other countries. Students who wish their medical education to be more comprehensive than that which is required for obtaining a diploma usually undertake the additional study before the presenting of their thesis, because they may present their thesis whenever it suits them best, and they usually wait

Digitized by Google

until their class-work is over and they are about to enter on practice. In Paris there are numerous advanced courses of instruction in subjects which are not required at the qualifying examinations, and they are attended by the above-mentioned section of students as well as by foreign medical men, already qualified to practise in their respective countries, who come to Paris in great numbers every year. Such courses will be found at the Faculty of Medicine, at the College of France, at the Faculty of Sciences, at the Pasteur Institute, at the Museum of Natural History, in the free lectures delivered at the École Pratique of the Faculty, and in the polyclinics of individual surgeons. At the Faculty of Medicine a private course of bacteriology is given in a laboratory of the École Pratique; it is not official, because there is not as yet a chair of bacteriology at the Faculty; it is conducted by M. Chantemesse, and consists of demonstrations, the use of the microscope, and the making of cultivations, including the study of the most important micro-organisms. Many of the official lectures delivered at the Faculty are, either from the nature of the subjects or from the advanced style in which they are treated, more adapted to medical graduates than to students; lectures to students are the special province of the assistant professors (*agrégés*), who confine themselves to instruction of the usually accepted kind. It may almost be said that medical education in Paris is embodied in the lectures delivered by the assistant professors, and that the lectures of the professors form a kind of school of a higher grade, free from anxiety about examinations and not occupied with matters of common knowledge. All the lectures of the professors and the assistant professors are public, and fees are charged for attendance. The professors' lectures, which are most largely attended by foreigners, are those on general pathology (Professor Bouchard), on Experimental and Comparative Pathology (Professor Chantemesse), on Forensic Medicine (Professor Brouardel), on Hygiene (Professor Proust), on Pathological Anatomy (Professor Cornil), &c. In addition there are at the hospitals four extensive courses on Clinical Medicine, four on Clinical Surgery, four on Nervous Diseases, two on Clinical Obstetrics, one on Syphilis, one on Affections of the Urinary Passages, one on Ophthalmology, and one on Diseases of Children, each of them constituting a small school in which the same organisation is repeated on a reduced scale, the professor discoursing on unusual and difficult cases to advanced students and practitioners who wish to increase their stock of knowledge, whilst the assistants and the *chefs de clinique* deliver more elementary expositions to the students. Moreover, in the majority of the hospitals the physicians and surgeons have of their own accord arranged for an analogous organisation, independent of the Faculty, and some of these courses are very popular on account of the excellence of individual teachers. Under this head may be mentioned the course on Gynæcology given by Dr Pozzi at the Hôpital Broca, that given by Dr. Doléris at La Pitié, that on Diseases of the Heart and Vessels given by Dr. Huchard at the Hôpital Necker, that on Obstetrics given by Dr. Budin at the Maternité, and those on Surgery given by Dr. Terrier and Dr. Lucas-Championnière, that on Diseases of the Stomach given by Dr. Debove, &c. This constitutes the clinical instruction obtainable in the hospitals; it is free, but is given by physicians and surgeons attached to the hospitals.

At the College of France there are numerous courses in the higher branches of various subjects, some of which have a bearing on medical questions—such, for instance, as that on Experimental Medicine (Professor d'Arsonval), that on the Natural History of Organised Bodies (delivered by Professor François Franck and developed into a course on Physiology), and that on General Anatomy (Professor Rouvier). This last-mentioned chair is in reality an advanced School of Histology; the lectures of the professor are public and free; there is also a special course lasting two months.

At the Museum of Natural History will be found courses on Comparative Anatomy (Professor Filhol) on General Physiology (Professor Gréhant), on Comparative Pathology (Professor Chauveau), and on Anthropology (Professor Hamy). All these lectures are delivered three times a week; they are open to the public and are free.

At the Faculty of Sciences there are lectures on Physiology (Professor Dastre), on Biological Chemistry (Professor Duclaux), and on the Evolution of Organised Beings (Professor Giard).

To all these chairs there are attached spacious laboratories in connexion with an organisation which unites them all under the name of the École des Hautes Études. Admission to these laboratories is always granted on application being made to the professor; in general there is no fee for admission, but any outlay required for the work that is undertaken has to be paid for. The workers are under the control of the professor, whether they undertake original investigation or merely seek to increase their knowledge of recognised subjects; in almost all the laboratories lectures are delivered by the assistants.

At the School of Anthropology there are free public lectures on Prehistoric Anthropology, Medical Geography, Ethnography, Ethnology, Biological Anthropology, Zoological Anthropology, Physiological Anthropology, Sociology, and Comparative Ethnography.

The Pasteur Institute has an admirably organised school of Microbiology and numerous laboratories arranged in five services, with accommodation for fifty persons. In order to be admitted to this school it is necessary to send an application to the institute, together with a description of the investigations or the work contemplated. A person so admitted can remain at the institute for an indefinite time provided that his work is continuous. For working in the laboratories there is a fixed charge of 50 francs (£2) a month, which, however, is remitted in the case of a certain number of students selected by the institute. The five laboratory services above mentioned are as follows: (1) Rabies (M. Grancher, M. Charrin, and M. Chantemesse); (2) general microbiology (M. Duclaux); (3) technical microbiology (M. Roux), together with laboratory for diphtheria (M. Martin); (4) microbiology applied to hygiene, including vaccins (M. Chamberland); and (5) morphological and comparative microbiology (M. Metchnikoff). The department of technical microbiology presided over by M. Roux is devoted to teaching as well as to original investigation. The course of instruction lasts six weeks, and admission to it is obtained by merely entering one's name and paying a fee of 50 francs (£2). As the places assigned to workers are at present not very numerous it is necessary to enter one's name two years in advance.

Finally, there are in Paris numerous private hospitals and polyclinics which are well attended by both students and practitioners. At some there are lectures open to all-comers and free. In others the medical men who attend accompany the physician or surgeon on his visit, and clinical instruction is given on the cases which happen to be under treatment; such is the case in the celebrated ophthalmological clinics (Galezowski, de Wecker, Landolt, &c.), as well as in those of laryngology and gynæcology. The laryngological clinic of Dr. Castex has recently been incorporated with the School of Medicine, and a fee is charged for instruction. With this exception it is in all cases sufficient to apply to the physician or surgeon for permission to attend his clinic, and the request is immediately granted.

GERMANY.

Post-graduate lectures and demonstrations are given in most of the universities of Germany. As a rule, their duration is from three to four weeks, the university vacation being the usual period. They are delivered partly by the ordinary professors and partly by *privat-docents* or lecturers. These lectures and demonstrations are not included in the official course of university instruction, they are private undertakings; but those who attend them are none the less freely admitted to the university laboratories and hospitals. Medical men wishing to join these courses have no formalities to comply with beyond entering their names and paying the fees for the lectures or the practical work which they happen to prefer. In the event of their intending to study in Berlin they should apply to Mr. Anders, Registrar of the Association for Post-graduate Study, Langenbeck House, N.W. Ziegelstrasse, 8. Lists of the lectures may be obtained from this gentleman, and may also be seen in the advertisement columns of the leading German medical journals.

AUSTRIA.

Courses of lectures, the attendance on which is limited to medical men in practice, are delivered in Vienna, but not in any other Austrian University. They were introduced on the initiative of Professor Wagner, who appointed two months (August and September) during which they are delivered in two series by the most eminent *privat-docents* and assistants of the Faculty. Each course lasts four weeks, and the fees vary from twenty gulden (£1 17*s.*) to fifty gulden (£4 13*s.*), according to the subject. The first series comprised last year the following courses: Pathological Anatomy (Dr. Albrecht and Dr. Stoerk), Bacteriology

Digitized by Google

(Dr. Ghon), Experimental Pathology (Dr. Biedl), Pharmacology (Dr. Hockauf), Internal Medicine (Dr. Hammerschlag, Dr. Czinner, and Dr. Türk), Neuro-pathology (Dr. Redlich), Diseases of Children (Dr. Franz), Ophthalmology (Dr. Topolanski, Dr. Hanke, Dr. Gruber, and Dr. Königstein), Laryngology (Dr. Grossmann, Dr. Rethi, Dr. Ebstein, and Dr. Koschier), Diseases of the Ear (Dr. Bing and Dr. Kaufmann), Dermatology and Syphilis (Dr. Rille and Dr. Spiegler), Obstetrics and Gynæcology (Dr. Wertheim, Dr. Woyer, Dr. Hink, Dr. Ludwig, Dr. Knauer, and Dr. Savor). The second series included the following courses:—Anatomy (Dr. Tandler), Pathological Anatomy (Dr. Kolisko and Dr. Albrecht), Bacteriology (Dr. Ghon), Experimental Pathology (Dr. Biedl), Forensic Medicine (Dr. Haberda), Internal Medicine (Dr. Pal, Dr. Schlesinger, Dr. Eisenschitz, and Dr. Sternberg), Surgery (Dr. Fraenkel), Dr. Schnitzler, and Dr. Friedländer), Ophthalmology (Dr. Bernheimer, Dr. Königstein, Dr. Sachs, and Dr. Wintersteiner), Diseases of the Ear (Dr. Bing, Dr. Pollak, Dr. Alt, and Dr. Kaufmann), Dermatology and Syphilis (Dr. Rille, Dr. Spiegler, and Dr. Zeissl), Obstetrics and Gynæcology (Dr. Lott, Dr. Braun, Dr. Herzfeld, Dr. Wertheim, Dr. Neumann, Dr. Woyer, Dr. Ludwig, Dr. Knauer, and Dr. Savor). These courses are likely to be preferred by medical practitioners to those delivered during the session from October to July, as they are not attended by students.

ITALY.

In many Italian medical schools special courses of instruction, clinical and theoretical, are now given to men who are already engaged in practice. Those who attend are mostly either on the one hand dispensary practitioners or divisional surgeons (medici condotti) or, on the other hand, graduates who take up special courses of study (particularly laboratory work) in order to become eligible for public health appointments under Government. For instance, at the University of Pavia a special series of lectures and demonstrations in hygiene has just been brought to a conclusion. The course was organised by Dr. Giuseppe Sormani, professor of the subject in the University, and was attended by graduates from all parts of Italy, attracted not only by the well-known expository power of the professor, but also by the preferential claim to sanitary posts conferred on all who have passed the examinations instituted by the Pavian school. Again, at Genoa, the post-graduate session of Dr. Maragliano, Professor of Clinical Medicine in that school, attracts an increasing attendance from other provinces besides those of the Alta Italia. In this course instruction is given in the refinements of sero-therapy, particularly as applied to pulmonary tuberculosis.

HUNGARY.

Foreign medical men who do not desire to obtain Hungarian qualifications, but merely to increase their knowledge by post-graduate study, will find no difficulty in pursuing their objects. They are allowed to enrol themselves among the "ausserordentliche Hörer" (students in special subjects) at a comparatively low fee, and are given every facility for practical study; vivisection, for instance, is amply provided for. All the lectures are delivered in the Hungarian language, but all the professors and teachers speak German, and some of them speak French and English as well. The cost of living in Budapest is nearly the same as in Vienna; the journey between the two towns takes five hours by railway

SOME OF THE CHIEF APPOINTMENTS HELD BY MEDICAL MEN.

Medical Officer to the Local Government Board.—This appointment is in the hands of the President of the Local Government Board for the time being, and has hitherto been filled by the promotion of one of the two assistant medical officers of that Board.

Medical Inspectors of the Local Government Board.—These appointments also are made by the President of the Local Government Board. Qualification and experience in public health are taken into consideration.

Medical Referees under the Workmen's Compensation Act, 1897.—This office was first constituted in the early part of 1898. The principal duties of the referees are to act as the advisers in medical matters of the committees, arbitrators, and county court judges who are empowered to decide all questions arising in proceedings under the Act. For this duty they are paid by the Treasury. The arrangement will eventually apply to the whole of the United Kingdom but at present arrangements have only been made for England and Wales. The fees payable by the Treasury vary from 1 guinea to 3 guineas and in addition occasions may arise where a workman will present himself to the medical referee for examination. Applications for the appointments should be addressed to the Home Secretary and sent under cover to the Private Secretary to the Secretary of State, Home Office, London, bearing on the envelope the words "Medical Referee," and should state the applicant's qualifications, age, &c., and the county court circuit to which he wishes to be attached. Preference, other things being equal, will be given to those applicants holding hospital appointments or to those who are not closely by the nature of their practice with the classes affected by the Act. (The full text of the circular from the Home Office will be found in THE LANCET of April 23rd, 1898, page 1137.)

Medical Officers to Poor-law Districts.—These appointments are made by the guardians of the union or parish in question, subject to the approval of the Local Government Board, which approval is primarily concerned with the medical and surgical qualifications of the persons appointed and the locality of their residences.

Public Vaccinators.—The conditions of appointment are the same as those already described for medical officers of Poor-law districts.

District Medical Officers of Health.—The appointments are made by the urban or rural district council in question, subject to the sanction of the Local Government Board, which sanction takes account of statutory qualifications, salary, area of district, &c.

County Medical Officers of Health.—The appointments are made by the respective county councils, with whom the question in all its details absolutely rests.

Lord Chancellor's Visitors in Lunacy.—There are two Visitors in Lunacy nominated by the Lord Chancellor. The appointments are usually bestowed on gentlemen who have distinguished themselves in the specialty.

Prison Medical Service.—Two medical officers are attached to each of the "first-class" prisons and one to several of the larger "second-class" prisons. They are required to devote their whole time to their official duties. The service is a small one and vacancies do not often occur. Forms of application can be procured from the Secretary to the Prison Department at the Home Office. The salary commences at £250 per annum, with free quarters, or an allowance in lieu thereof.

Medical Officers of the Mercantile Marine.—The Merchant Shipping Act, 1894 directs (Section 209) that every foreign-going ship having 100 persons or upwards on board shall carry a duly qualified medical practitioner. Ship's medical officers, however, are more often appointed under the part of the same Act relative to "emigrant ships." For the purposes of the Act an emigrant ship is defined as one which carries more than 50 steerage passengers, and a steerage passenger is defined as one who is not a cabin passenger. Section 303 provides that a medical practitioner shall be carried on board an emigrant ship where the number of steerage passengers exceeds fifty, and also where the number of persons on board (including cabin passengers, officers, and crew) exceeds 300. A medical practitioner shall not be considered to be duly authorised for the purposes of this Act unless (*a*) he is authorised by law to practise in some part of Her Majesty's dominions, or in the case of a foreign ship in the country to which that ship belongs; and (*b*) his name has been notified to the emigration officer at the port of clearance, and has not been objected to by him; and (*c*) he is provided with proper surgical instruments to the satisfaction of that officer. If any person proceeds or attempts to proceed as medical practitioner in any emigrant ship without being duly authorised, he shall be liable to a fine not exceeding £100. Surgeons in charge of passenger ships should keep a record of any sickness that occurs on the voyage, whether among saloon passengers, emigrants, or crew, and they are requested to report the same to the emigration officer at the end of the voyage. The remuneration for these appointments is extremely variable, ranging from a free passage to the port of destination to a salary of £10 a month during continuance in the service. The appointments are of course made by the various firms of shipowners and the applicants are sometimes numerous.

SESSION 1898–99.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council, and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

The Preliminary Examination in General Education, required to be passed previously to registration as a Medical Student, shall be as follows:—

"1. English language, including grammar and composition. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Mathematics, comprising (*a*) arithmetic, (*b*) algebra, as far as simple equations, inclusive; (*c*) geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects: (*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other modern language, (*f*) logic."

The Council will not in future accept any certificate of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been *passed at the same time.*

Professional Education.—For those who commenced study after Jan. 1st, 1892, the course of professional study after registration shall occupy at least five years. The Final examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student the applicant producing satisfactory evidence that he has passed them:—

I.—UNIVERSITIES IN THE UNITED KINGDOM.

University of Oxford.—Junior Local Examinations. Senior Local Examinations. Responsions. Moderations. Final Examination for a degree in Arts.

University of Cambridge.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Previous Examination. General Examination. Final Examination for a degree in Arts.

University of Durham.—Examination for Certificate of Proficiency. Preliminary Examination in Arts for Graduation in Medicine and Science. Final Examination for a degree in Arts.

University of London.—Matriculation Examination. Final Examination for a degree in Arts or Science.

Victoria University.—Preliminary Examination. Entrance Examination in Arts. Final Examination for a degree in Arts or Science.

University of Wales.—Matriculation Examination. Final Examination for a degree in Arts.

University of Edinburgh.—Local Examinations (Senior and Junior). Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science.

University of Aberdeen.—Local Examinations (Senior and Junior). Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science.

University of Glasgow.—Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science.

University of St. Andrews.—Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Final Examination for a degree in Arts or Science or for the diploma of L.L.A.

University of Dublin.—Public Entrance Examination. Examination for the first, second, third, or fourth year in Arts. Final Examination for a degree in Arts.

Royal University of Ireland.—Matriculation Examination. Final Examination for a degree in Arts or Science.

Oxford and Cambridge Schools Examination Board.—Lower certificate (to include all the required subjects at one time). Higher certificate (to include the required subjects).

II.—MEDICAL LICENSING BODIES.

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination.[1]

III.—EDUCATIONAL BODIES OTHER THAN UNIVERSITIES.

College of Preceptors.—Examination for a First Class Certificate or Second Class Certificate of First or Second Division. Preliminary Examination for Medical Students.

Intermediate Education Board of Ireland.—Junior Grade Examination; Middle Grade Examination; Senior Grade Examination.

Educational Institute of Scotland.—Preliminary Medical Examination.

Scotch Education Department.—Leaving Certificates in Lower and Higher Grades and in Honours.

IV.—INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES.

The Certificates from Indian, Colonial, and Foreign Universities and Colleges must contain evidence "that the Examination has been conducted by or under the authority of the Body granting it, includes all the subjects required by the General Medical Council, and states that all the subjects of Examination have been passed in at one time; and copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classic Oriental Language may be accepted instead of an Examination in Latin."

H. E. Allen, LL.B., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 48, George-square, Edinburgh.—S. W. Wilson, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS OF THE MEDICAL EXAMINING BODIES IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.[2]

THERE are two degrees in Medicine, B.M. and D.M., and two degrees in Surgery, B.Ch. and M.Ch.

The B.M. and B.Ch. degrees are granted to those members of the University who have passed the Second Examination. Graduates in Arts (B.A. or M.A.) are alone eligible for these two degrees. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Animal Morphology and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology unless he has obtained a first or second class in

[1] The Council has recommended that this examination be discontinued.

[2] No returns until these sheets were in the press.

Digitized by Google

Animal Physiology in the Natural Science School; Human Anatomy, and Materia Medica with Pharmacy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, Physics and Chemistry, December and June; Animal Morphology and Botany, December and March; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of B.M. subsequently to the end of Trinity Term, 1886, provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M. Examination.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first. Before admission to the Second Examination candidates must present Certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination every year by some of the Colleges. Notices of vacancy, &c., are published in the *University Gazette*. In February there is competed for annually, by those who, having obtained a first-class in any school (Moderations or final), or a Scholarship or Prize open to general competition in the University, have passed all the examinations for the degree of B.A., one Radcliffe Travelling Fellowship. It is tenable for three years and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject including Physiology or Pathology.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1894, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University; from the Regius Professor of Medicine; and from the Professors in the several departments of science.

The Lecturers for the various subjects are as follows:—Regius Professor of Medicine: J. S. Burdon Sanderson, D.M. Pathological Histology and Practical Bacteriology: The Lecturer on Pathology, J. Ritchie, D.M. Edin. Professor of Human Anatomy: A. Thomson, M.A. Waynflete Professor of Physiology: F. Gotch, M.A.; Advanced Course: the Lecturer on Physiology, J. S. Haldane, M.A. Practical Physiology and Histology: G. Mann, D.M. Edin. Lichfield Lecturer in Clinical Medicine: G. J. Wilson, M.A., D.M. Dub. Lichfield Lecturer in Clinical Surgery: W. L. Morgan, M.A. Organic Chemistry in Relation to Medicine, &c., followed by Practical Work: Aldrichian Demonstrator, W. W. Fisher, M.A., and J. E. Marsh, M.A. Lecturer in Materia Medica, J. E. Marsh, M.A. Linacre Professor of Comparative Anatomy, E. Ray Lankester, M.A. Elementary Animal Morphology (Practical): the Aldrichian Demonstrator, W. B. Benham, M.A., and assistants. Sherardian Professor of Botany: S. H. Vines, M.A. Waynflete Professor of Chemistry: W. Odling, M.A. Inorganic Chemistry: A. G. Vernon Harcourt, M.A. Laboratory Instruction: W. W. Fisher, M.A., J. Watts, M.A., V. H. Veley, M.A., and J. E. Marsh, M.A. Professor of Experimental Philosophy: R. B. Clifton, M.A. Instruction in Practical Physics: R. B. Clifton, M.A., J. Walker, M.A., W. F. S. Churchill, B.A., and J. C. Alsop, B.A. Elementary Heat and Light: R. E. Baynes, M.A. Elementary Mechanics: F. J. Smith, M.A.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., which may, and should if possible, be done immediately on coming into residence in October, or, what is better, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Cambridge Senior Local Examinations before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine (M.B.)* five years of medical study are required. This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection is abundant and the laboratories for Pathology, Bacteriology, and Pharmacology are well equipped.

There are three examinations for M.B. The *first* includes Chemistry and other branches of Physics, and Elementary Biology. These parts may be taken together or separately. The *second* in Human Anatomy and Physiology and in Pharmaceutical Chemistry. These may be taken together or separately. The *third* may also be taken in two parts—viz., (1) Principles and Practice of Surgery (with Operative and Clinical Surgery) and Midwifery and Diseases of Women; and (2) Pathology, Principles and Practice of Medicine, including Pharmacology and Therapeutics, Elements of Hygiene, Medical Jurisprudence and Mental Diseases. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself on some subject approved by the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of the third M.B. examination candidates who have passed both parts of that examination are admitted to the registrable degree of *Bachelor of Surgery (B.C.)* without separate examination and without keeping an Act.

The degree of *Doctor in Medicine* may be taken three years after that of M.B. or four years after that of M.A. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools, with *viva-voce* examination; and an extempore Essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

For the degree of *Master in Surgery (M.C.)* the candidate must have passed all the examinations for B.C. He is required either (1) to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery, and to write an extempore Essay on a Surgical Subject; or (2) to submit to the Medical

Digitized by Google

Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.C.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, and Pharmaceutical Chemistry may be obtained upon sending a stamped directed envelope to the Registrary, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examination.*—Candidates for any degree in this University must have passed the Matriculation Examination. No exemption either from Matriculation or from subsequent examinations is allowed on account of degrees obtained at other Universities or of examinations of other examining bodies that may have been passed. The examinations take place twice in each year—on the second Monday in January and the second Monday in June; and may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies. Every candidate must, on or before April 25th for the June examination, and on or before Nov. 25th for the January examination, apply to the Registrar for a form of entry, which must be returned on or before May 1st or Dec. 1st respectively, accompanied by a certificate showing that the candidate has completed his sixteenth year and by his fee for the examination. A certificate from the Registrar-General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, is required in every case in which it can possibly be obtained. In other cases a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate, if of full age, will be accepted. As candidates cannot be admitted after the list is closed, any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Registrar, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2, and if he withdraws his name, or fails to present himself at the examination, or fails to pass it, the fee shall not be returned to him, but he shall be allowed to enter for any subsequent matriculation examination upon payment at every such entry of an additional fee of £1, provided that he comply with the other regulations. Candidates must show a competent knowledge of: 1. Latin. 2. English Language, History to the end of the seventeenth century, with the Geography relating thereto. 3. Mathematics (Elementary). 4. General Elementary Science. 5. Any one of the following languages or sciences: Greek, French, German, Sanskrit, Arabic, Elementary Mechanics, Elementary Chemistry, Elementary Sound, Heat, and Light, Elementary Magnetism and Electricity, Elementary Botany. (No credit will be given for more than one of these subjects, and candidates desiring to be examined in Sanskrit or Arabic must give two months' notice to the Registrar. The examination in Botany is only held in the United Kingdom. Candidates in any one of the optional Branches of Science will find it an advantage to have obtained some elementary instruction in the practical use of apparatus.) A pass certificate signed by the Registrar is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate. The first six candidates in the Honours Division, of not more than twenty years of age at the commencement of the examination, shall respectively receive an exhibition or a prize. Any candidate obtaining a place in the Honours Division at the matriculation examination in January shall be admissible to the intermediate examination either in Arts or in Science in the following July.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations, and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Registrar of the University, who will then make all necessary arrangements. Besides the University fee, a fee usually varying from £1 to £2 is charged by the local authorities, and must be paid *at the local centre* immediately before the commencement of the several examinations. The answers of the candidates at the provincial examinations are reviewed by the examiners at the same time as the answers of the candidates examined in London, and a list of the candidates who have passed at each provincial examination is published, at the time fixed by the regulations, at the place where such examination has been held.

Preliminary Scientific (M.B.) Examination.—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M.B. degree. Candidates must have passed the matriculation examination. The examination takes place twice in each year, once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. Every candidate must apply to the Registrar for a form of entry on or before May 24th for the July examination, or on or before Dec. 15th for the January examination, which must be returned on or before July 1st and Dec. 22nd respectively, accompanied by the candidate's fee of £5. The subjects of the Preliminary Scientific Examination are divided into two sections: (1) Chemistry and Physics, (2) General Biology. Chemistry includes a written examination in Inorganic Chemistry and a *viva-voce* examination in Qualitative Analysis. Physics implies a knowledge of acoustics, heat, magnetism, electricity, and optics. General Biology comprises a knowledge of the elements of zoological (vertebrate or invertebrate) and botanical morphology, physiology, and embryology. Candidates shall be allowed to enter for the whole examination or for either section. Candidates who present themselves for the two sections together shall be credited with either section in which they may have passed, although they may have failed to pass in the other, but no such candidate shall be placed in the Honours List. Candidates must bear in mind that the standard of attainment for the Honours examination is much higher than that for the Pass examination; and they should therefore exercise due caution in making their choice, to which they will be required to adhere. Candidates for Honours in Botany and Zoology must take the Pass examination in General Biology; in other respects no candidate may take both the Pass and the Honours papers in the same subject. The fee of £5 covers the whole of the examination, whether taken altogether or in sections.

Provincial Examinations for the Preliminary Scientific (M.B.) Examination.—Pass examinations are held in July only at nearly the same places as those appointed for the June Provincial Matriculation examinations. The practical examinations in chemistry are conducted at the provincial centres, but all candidates must attend at the University for the practical examinations in Physics and Biology.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University not less than five years previously. 2. To have passed the Preliminary Scientific (M.B.) Examination not less than four years previously. 3. To have been engaged in his professional studies during five years subsequent to matriculation and four years subsequent to passing the Preliminary Scientific Examination at one or more of the medical institutions or schools recognised by this University, one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. The subjects of the examination are Anatomy, Physiology and Histology, Organic Chemistry,[3] Materia Medica, and Pharmaceutical Chemistry. The standard of attainment required for Honours is much higher than for a Pass. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, sub

[3] In and after 1899 the Summer examination will commence on the first Monday in July.

Digitized by Google

sequently to having passed the Preliminary Scientific Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Physiology and Histology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases Peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry, in applying tests for discovering the adulteration of articles of the Materia Medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination. Fee for this examination, £5.

M.B. Examination.—The M.B. Examination takes place twice in each year—once for Pass and Honours, commencing on the last Monday in October, and once for Pass candidates only, commencing on the first Monday in May. The subjects of the examination are General Pathology, General Therapeutics, Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. No candidate will be admitted to this examination within twenty-one months of the time of his passing the Intermediate Examination unless he be a registered medical practitioner of not less than three years' standing, in which case he must produce a certificate of having gone through the required course of training at some time previously. Every candidate must produce certificates:—1. Of having passed the Intermediate Examination. 2. Of having attended a course of lectures on each of two of the subjects enumerated above in the regulations for that examination for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine, including Infectious Diseases and Lunacy. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination in Medicine, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The fee for this examination is £5.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery and of having operated on the dead subject. The subjects of the examination are Surgery and Pathology and Surgical Anatomy. Fee £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year and commences on the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University: (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Mental Physiology (especially in its relations to mental disorder) and Surgery. Any candidate for the degree of M.S. may transmit to the Registrar, not later than Oct. 1st, a printed Dissertation, Thesis, or Commentary, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Surgical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Surgery. The fee is £5.

Doctor of Medicine.—The examination for this degree takes place once in each year and commences on the first Monday in December. Candidates may present themselves for examination either in Medicine or State Medicine. Those presenting themselves for the M.D. Examination in Medicine must produce certificates to the following effect:—1. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University: (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of their profession; (*c*) or of having been engaged during five years in the practice of their profession, either before or after taking the degree of Bachelor of Medicine in this University. 2. Of moral character, signed by two persons of respectability. One year of attendance on Clinical or Practical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. Candidates presenting themselves for the M.D. Examination in State Medicine must produce certificates to the following effect:—1. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this university: (*a*) to State Medicine during two years, including six months' practical instruction in a laboratory and six months' outdoor sanitary work; (*b*) or to State Medicine during one year, and of having held for a period of two years the position of medical officer of health in any sanitary district; (*c*) or of having held for a period of three years the position of medical officer of health in any sanitary district. 2. Of moral character. One year of attendance on State Medicine or one year of holding the position of medical officer of health will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Medicine (or State Medicine) and Mental Physiology. Any candidate for the degree of M.D. may transmit to the Registrar, not later than Oct. 1st, a printed Thesis, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Medical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Medicine (or State Medicine). The fee is £5.

UNIVERSITY OF DURHAM.

One Diploma and six degrees are conferred—viz., the Diploma in Public Health and the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene. These degrees are open both to Men and Women.

For the degree of *Bachelor in Medicine* (*M.B.*) there are four professional examinations.

The subjects of the First Examination are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics.

The subjects for the Second Examination are—Anatomy,

Digitized by Google

Physiology, Materia Medica, Therapeutics, Pharmacology, Pharmacy.

The subjects for the Third Examination are—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.

The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children.

N.B.—It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England will be exempt from the First Examination of the University, except in the subjects of Elementary Anatomy, Chemistry, and Physics, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom will be exempt from the First Examination of the University, except in the subjects of Chemistry and Physics. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery (B.S.)* every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery (M.S.)* candidates must not be less than twenty-four years of age and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham and must have been engaged for at least two years subsequent to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice.

The subjects of examination are :—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

For the degree of *Doctor in Medicine (M.D.)* candidates must be not less than twenty-four years of age and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Medicine in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must write an Essay, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the Essay.

The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under forty years of age and shall have been in active practice for fifteen years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession, and if they have not passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register, they shall be required to pass in Classics and Mathematics. Candidates who have passed an examination in Arts previously to being placed on the Register are required to pass an examination in Latin. They will be examined in the Principles and Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery, Midwifery, and Diseases of Women and Children, Pathology (Medical and Surgical), Anatomy (Medical and Surgical), Medical Jurisprudence, and Toxicology. The fee will be fifty guineas, of which twenty guineas will be returned if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees must give at least twenty-eight days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-on-Tyne.

[4] This regulation will not apply to candidates registering as medical students on or after Oct. 1st, 1896. Such candidates must pass in all the subjects of the first examination.

VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds.

Matriculation, which consists in signing the University Register, must precede entry upon any course of study in a College of the University, if that course is to be counted towards the required minimum of attendance for a degree. Those only can matriculate who are registered students of a College of the University.

Four degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[5]

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the First M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations: the First Examination, the Second Examination, and the Final Examination.

The First Examination.—The subjects of examination are as follows :—(1) Chemistry; (2) Elementary Biology; (3) Physics. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Physics and Chemistry; Part 2, Biology; and the candidates may pass in these parts separately.

The Second Examination.—The subjects of examination are as follows :—A : (1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology; B : (3) Materia Medica and Pharmacy. Candidates may pass in A or B separately.

The Final Examination.—The subjects of examination are as follows :—(1) Pharmacology and Therapeutics. (2) General Pathology and Morbid Anatomy. (3) Forensic Medicine and Toxicology, and Public Health. (4) Obstetrics and Diseases of Women. (5) Surgery, Systematic, Clinical and Practical. (6) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children.

Candidates may either present themselves in all the six subjects of examination on the same occasion or may pass the examination in two parts, the first part consisting of *two* or *three* of the subjects (1), (2) and (3), the second part of the remaining subjects.

Candidates who fail to satisfy the examiners in the first part must either present themselves again in the subjects as

[5] The examinations at present recognised are:—1. The Preliminary Examination of Victoria University, provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions of the University of Oxford. 5. The Leaving Certificate Examination (Higher) and Local Examinations (Honours) of the Oxford and Cambridge Boards, provided that they include Latin, English, Mathematics, and Elementary Mechanics. 6. The Final Examination for Graduation in Arts of any university in Great Britain and Ireland.

Digitized by Google

selected or in all the three subjects of the First part or in all the six subjects of examination.

Candidates for the first part of the examination must have completed the *fourth winter* of medical study.

Candidates for the second part of the examination, or for the whole examination, must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a printed Dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his Dissertation shall have been recommended by the General Board of Studies to the Council for acceptance. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; (6) Pathology and Bacteriology.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

Subject to regulations to be made from time to time by the University Court, the University may also confer diplomas in special branches of medical and surgical practice on graduates of the University in Medicine and Surgery.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German: Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than eighty patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months. These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures. A similar course of clinical medicine during a course or courses extending over not less than nine months is required. The candidate must have attended a course of instruction in Mental Diseases given by the University Lecturer, or by a recognised Teacher, consisting of not less than six Class-room meetings for lectures and demonstrations and ten meetings in the Wards of a recognised Asylum for the insane. The candidate must have attended a course of twenty-five meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. The candidate must have attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries. He must have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital for a period of six months in each case; and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary, Post-mortem Examinations, Fevers, Diseases of the Eye, Operative Surgery, and one of the two following, viz.—Diseases of Children, and Diseases of the Larynx, Ear, and Nose, or such other special departments as may from time to time be determined. The candidate must have attended, under the superintendence of a registered medical practitioner, twelve cases of labour, or such additional number as the Senatus, with the sanction of the University Court, may from time to time determine; or have attended for three months the practice of a lying-in hospital, or of the maternity department of a general hospital or other public charitable institution, and have conducted personally six or such an additional number of cases of labour as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination.

Next, with respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study, sixteen in number—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in some Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to, a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Each candidate is examined, both in writing and orally, and clinically where the nature of the subject admits:—First, in Chemistry, Zoology, Botany, and Physics; second, in Anatomy, Physiology, Materia Medica and Therapeutics; third, in Pathology, and Medical Jurisprudence and Public Health; and fourth, in Surgery, Medicine, Midwifery, and clinically in Medicine and Surgery in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes. Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their third year. Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2s., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First

Digitized by Google

Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6s.; for the Second Division (Anatomy, Physiology, and Materia Medica and Therapeutics), £6 6s.; for the Third Division (Pathology and Medical Jurisprudence and Public Health), £4 4s.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, and Midwifery), £6 6s. The fee to be paid for the degree of Doctor of Medicine is £10 10s., and the fee to be paid for the degree of Master of Surgery is £10 10s.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to examination only candidates whose course conforms to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but eight of the subjects other than clinical must be taken in this or some other recognised university entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations four degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject, and on passing the Preliminary Examination candidates must register as medical students in the books of the General Medical Council. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination but must do so at not more than two occasions. For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months' courses, or alternatively one five months' course and two courses of two and a half months. The minimum of attendance in the first four years includes five months' courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics, Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following:—Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least eighty patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and must have had six months' out-door practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (twenty-five meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least twelve cases of labour, or three months of the practice of a Lying-in Hospital, six cases being personally conducted. The University also requires further study in Post-Mortem Examinations, Fevers, and Ophthalmology, and recommends study in other special subjects. If a candidate has completed in a University of the United Kingdom a course of study and passed an examination in Botany, Zoology, Physics or Chemistry, qualifying for a degree in Science or in Arts, he is held to have passed the examinations in such subject or subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under twenty-four years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The fees for M.B. and Ch.B. are £23 2s. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3s. and the present fees for hospital attendance are £21. The fee for M.D. is £10 10s. (stamp duty being now abolished), and for Ch.M. £10 10s.

The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Belvidere Hospital, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Eye, the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary.

Bursaries and Prizes to the annual amount of about £820 are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1600 may be held by medical students who have gone through the Arts course.

Graduations under the regulations for the curriculum of five years introduced in 1892 began in July, 1897. Formerly, students graduated as M.B. and C.M. on a four years' curriculum under the old regulations, and such graduates may afterwards proceed to the degree of M.D. by Thesis after passing a somewhat more stringent preliminary examination, including Greek. Supplementary regulations passed in 1895 by the Scottish Universities Commissioners allow those holding the degrees of M.B. and C.M. under the former regulations to proceed to the new M.D. by Examination and Thesis in the same manner as those who obtain the double Bachelorship under the new regulations. Candidates electing to proceed in this way will be freed from the preliminary examination in Greek.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the Universities of Edinburgh and Glasgow.

Professional Examinations will be held twice in each year—namely, in March and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1 1s.; summer session alone, 10s. 6d.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: General Fever Hospital; Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom only, after a special examination. The diploma can be entered on the Register of the General Medical Council.

Application for further information should be addressed to the Secretary of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

The following are extracts from the Regulations for Degrees in Medicine contained in Ordinance No. 45 (St. Andrews, No. 4) of the Commissioners under the Universities (Scotland) Act, 1889. These regulations came into force on April 19th, 1897. Four Degrees in Medicine and Surgery shall be conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical

Digitized by Google

studies each student shall pass a Preliminary Examination in, (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects:—(*α*) Greek, (*β*) French, (*γ*) German, (*δ*) Italian, (*ε*) any other Modern Language, (*ζ*) Logic. A degree in Arts or in Science in any of the universities of the United Kingdom and in some colonial or foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the final examination for the Diploma of L.L.A.

Candidates for the degree of Bachelor of Medicine and Bachelor of Surgery must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than eighty patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery (twelve cases of labour), and Vaccination.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court.

Women shall be admitted to graduation in Medicine, subject to the provisions of Ordinance No. 18 [General No. 9—Regulations for the Graduation of Women and for their Instruction in the Universities]: Provided always that every candidate for graduation shall produce evidence of having satisfied the conditions herein laid down with respect to the Preliminary Examination, and shall be examined in all the subjects necessary for graduation by the Examiners of the University of St. Andrews. All the classes necessary for graduation shall be taken in the University of St. Andrews, except in so far as instruction obtained elsewhere is allowed by the said Ordinance.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., First, in Botany, Zoology, Physics, and Chemistry: Second, in Anatomy, Physiology, and Materia Medica; Third, in Pathology, and Forensic Medicine and Public Health; Fourth, in Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 10 guineas, exclusive of any stamp duty which for the time may be exigible. The fee to be paid for the degree of Master of Surgery shall be 10 guineas.

The following seven qualifying classes are now being taught at the United College, St. Andrews: (1) Physics, (2) Botany, (3) Natural History (Zoology), (4) Chemistry, (5) Anatomy, (6) Physiology, and (7) Materia Medica. These classes furnish two very complete Anni Medici—the period of university residence required by the four Scottish Universities for graduation in Medicine. Owing to the munificence of the present Lord Rector—the Marquis of Bute—an important addition to the existing Medical Buildings at St. Andrews is being made at a cost of £12,000. The three last years of the medical curriculum can be taken at University College, Dundee, or any convenient recognised Medical School in the United Kingdom. Qualifying courses in Medicine and Surgery are given at University College, Dundee. It is hoped that medical students who spend their two residential years at St. Andrews will return to their Alma Mater and graduate there.

Scholarships and Bursaries.—The following Scholarships and Bursaries for male and female Medical and Science Students are available at the United College, St. Andrews: One Scholarship of the annual value of £150, tenable for two years. A second Scholarship of the annual value of £100, tenable for one year and occasionally for two years. (The second Scholarship can be taken by students studying Physiology, Zoology, and Botany, in connexion with the Bachelor of Science degree.) Twelve Berry Bursaries for male Medical students of the annual value of £20 each, for two years. Fourteen Taylour Thomson Bursaries for female Medical students of the annual value of from £20 to £30 each, tenable for one or two years—viz.: Three Taylour Thomson Bursaries of the annual value of £30 each, tenable for two years; two of the annual value of £20, tenable for two years; four of the annual value of £25 each, tenable for one year; four of the annual value of £25, tenable for two years; and one of the annual value of £20, tenable for one year. The Bursaries are awarded in the order of merit, the most valuable ones being given to those students who obtain the highest marks in the Preliminary Examination, and who are prepared to take two Anni Medici at the United College, St. Andrews.

For further particulars apply to the Dean of the Medical Faculty, University of St. Andrews, N.B.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be concurrent with the medical course, and the B.A. degree need not be taken before the final medical examination, but the medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics, Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Dublin Hospital (one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum may be counted as one year spent in such Dublin hospital); (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months'; (5) Practical Midwifery with Clinical Lectures, including not less than thirty cases, six months'; (6) Ophthalmic Surgery, three months'. Two examinations have to be passed. The Previous Medical or Half M.B. Examination, including Physics and Chemistry, Botany and Zoology, Anatomy and Institutes of Medicine (Practical Histology and Physiology), may be passed when credit has been obtained for the corresponding subjects, and these may be taken separately if desired. The Final Examination is subdivided into five sections, comprising Applied Anatomy (Medical and Surgical), Applied Physiology, Jurisprudence

Digitized by Google

and Hygiene, Materia Medica and Therapeutics, Medicine, Surgery, Pathology, Midwifery, Gynæcology, Obstetrical Anatomy, Clinical Medicine, Mental Diseases, Clinical Surgery, Operations, Clinical Ophthalmology. The first seven of these subjects may be passed in the fourth year and the last eight in the fifth year. Fee for the *Liceat ad Examinandum*, £10. Fee for the degrees, £17.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis before the Regius Professor of Physic. Total amount of fees for this degree, £13.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass an examination in the following subjects:—1. Clinical Surgery. 2. Operative Surgery. 3. Surgical Pathology. 4. Surgery. 5. Surgical Anatomy (on the dead subject), and one of the following optional subjects:—1. Surgery in one of the following branches—viz., Ophthalmic and Aural, Gynæcological, and Dental. 2. Mental Disease. 3. Medical Jurisprudence and Hygiene. 4. Advanced Anatomy and Physiology. 5. Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. examinations, and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery.[6] He is then required to pass an examination in the following subjects:—1. Practice of Midwifery. 2. Gynæcology. 3. Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. Fee for the degree of Master in Obstetric Science, £5.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in Medical Studies. The Course and Examination necessary for the diplomas are the same as for the degrees, except that the candidate is not required to attend the Lectures on Botany and Zoology, nor to pass the Previous Medical examination in those subjects. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the Lectures on Botany and Zoology, passing the Previous Medical examination in those subjects, and paying the degree fees. Fee for the *Liceat ad Examinandum*, £10. Fee for the diplomas in Medicine, Surgery, and Midwifery, £11.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, Prizes and Scholarships in this University are open to students of either sex.

Candidates for any degree in this University must have passed the Matriculation Examination. Students from other universities and colleges are included in this rule.

The following degrees, &c., are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics and Master of Obstetrics; in Sanitary Science, a special diploma; and in Mental Disease, a special diploma.

The Medical Examinations, except that for the diploma in Sanitary Science, will be held twice yearly—viz., in April and in October. The examination for the diploma in Sanitary Science will be held in July.

The course for degrees in Medicine, &c., is of at least five years' duration.

The First Examination in Medicine.—Students may be admitted to this examination after the lapse of one academical year from the time of their matriculation. They must also have previously passed the First University Examination. The subjects of this examination are Natural Philosophy, Theoretic Chemistry, Zoology and Botany. The examination in each subject will comprise two parts:—1. A written examination. 2. Practical work and oral examination. For Chemistry the practical examination takes place at the close of the second year. Particular weight will be given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination in Arts did not obtain 30 per cent. of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of those languages will involve the loss of the examination.

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the second year of the medical curriculum. The subjects for this examination are Anatomy, Physiology, and Practical Chemistry.

The Third Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of the medical curriculum. The subjects for this examination will be Anatomy, Physiology, and Materia Medica (Pharmacology).

The Examination for the Medical Degrees.—Students will be admitted to this examination after the lapse of two academical years from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the fourth year. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology, Mental Diseases, Medical Jurisprudence and Hygiene. (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology. (*c*) Midwifery and Gynæcology, with Diseases of Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M.B., B.Ch., and B.A.O., receive a certificate of having passed a qualifying examination in the subjects of Medicine, Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to the Medical Degrees.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of three academical years from the time of obtaining the degree of M.B. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss all the questions arising thereon.

The M.Ch. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination on Surgical Instruments and Appliances; and (*d*) an examination in Operative Surgery.

The Mastership in Obstetrics.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children and the Use of Instruments and Appliances and will include—(*a*) a written examination; (*b*) a clinical examination as far as practicable; (*c*) an oral examination, with practical illustrations; and (*d*) an examination on Instruments and Appliances.

[6] Existing graduates in Medicine of the standing of M.D. are not required to attend this course.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.[7]

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after Jan. 1st, 1892.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth. (One of the five years may be spent in

[7] The diploma of Member of the Royal College of Surgeons of England and the Licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to Oct. 1st, 1884.

Digitized by Google

an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology.)

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry and Physics, Practical Pharmacy, and Elementary Biology. A candidate may take this examination in three parts at different times. A candidate will be admitted to examination in Chemistry and Physics and Elementary Biology before registration as a medical student, and to examination in Practical Pharmacy on producing evidence of having been registered as a medical student by the General Medical Council, *or he may take Pharmacy* at any time during the curriculum. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the First Examination are as follows: For the whole examination, £10 10*s.*; for re-examination after rejection in Part I. £3 3*s.*, and for re-examination in each of the other parts, £2 2*s.*

The subjects of the Second Examination are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as Medical Students and after the lapse of not less than six months from the date of passing Parts I. and III. of the First Examination.

A candidate referred on the Second Examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the Second Examination are: £10 10*s.* for the whole examination, and £6 6*s.* for re-examination after rejection.

The subjects of the Third or Final Examination are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases Peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases of Women at any time after the completion of the fourth year of professional study, not less than one year after passing the Second Examination, on production of the required certificates. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to the several parts of the Third, or Final Examination—viz., in Medicine, of having attended Lectures on Medicine, Pathology including Bacteriology, Pharmacology and Therapeutics, Forensic Medicine, and Public Health; Practical Instruction in Medicine; Medical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post Mortem Room during twelve months; Clinical Lectures on Medicine during nine months; of having discharged the duties of Medical Clinical Clerk; Practice of a Fever Hospital and Clinical Demonstrations at a recognised Lunatic Asylum; in Surgery, of having attended Lectures on Surgery and Pathology including Bacteriology; Practical Instruction in Surgery; of having performed operations upon the Dead Subject; Surgical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post Mortem Room during twelve months; Clinical Lectures on Surgery during nine months; of having discharged the duties of Surgical Dresser, and Clinical Instruction in Ophthalmology; in Midwifery of having attended Lectures on Midwifery; Practical Instruction in Midwifery; Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women; and of attendance on 20 Labours.

Fees for admission to the Third or Final Examination are as follows: For the whole examination, £15 15*s.* Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s.*; for re-examination in Practical Pharmacy (if taken at this examination), £2 2*s.* Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5*s.* Part III. For re-examination in Midwifery and Diseases Peculiar to Women, £3 3*s.*

A candidate referred on the Third or Final Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

ROYAL COLLEGES OF SURGEONS AND PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess another and opposite qualification in Medicine or Surgery, as the case may be, recognised by them. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—1. Candidates who commenced medical study *before* Jan. 1st, 1892, must have been engaged in professional study during forty-five months from the date of registration as medical students by the General Medical Council, which period shall include not less than four winter sessions' attendance at a recognised medical school. 2. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Anatomy, during at least six months; Practical Anatomy, twelve months; Chemistry, six months; Practical or Analytical Chemistry, three months; Materia Medica, three months; Physiology, six months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, three months; Medical Jurisprudence, three months; Pathological Anatomy, three months. The six months' courses delivered in Scotland must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than fifty lectures. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 3. The candidate must also produce the following certificates:—(*a*) Of having attended not less than six cases of labour, three of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the

Digitized by Google

superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the Medical and Surgical practice of a public general hospital containing on an average at least eighty patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended for six months (or three months, with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital, or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second Examinations. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination, and of having performed operations under the teacher's inspection, during a period of not less than six weeks.

Candidates shall be subjected to three Professional Examinations, and they may enter either for the whole of an Examination or for a division thereof.

First Examination.—The First Examination shall embrace the two divisions of (1) Chemistry and (2) Elementary Anatomy and Histology, and shall take place not sooner than the end of the first year, including the period of a winter and a summer session. For the whole Examination taken at one time the sum of £5 5*s.* must be paid to the inspector of certificates not later than one week preceding it, after which no candidate will be entered. After rejection, for re-entry in all subjects, £3 3*s.*; for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s.*; for entering for one division of subjects separately, £3 3*s.*; and for each re-entry after rejection, £2 2*s.* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the First Examination before any of the boards specified in the Regulations will be exempt from examination in such subjects.

Second Examination.—The Second Examination shall embrace the three subjects of (1) Anatomy, (2) Physiology, (3) Materia Medica and Pharmacy, each of which shall constitute a division of the examination, and may be entered for separately. The examination shall not take place before the termination of the summer session of the second year of study, including two winters and two summers. The fees for admission to this examination, payable not later than one week before the day of examination, are as follows:—For the whole examination, £5 5*s.*; after rejection for re-entry in all subjects, £3 3*s.*; for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s.*; for entering for one subject separately, £2 2*s.*; and for each re-entry therein after rejection, £2 2*s.* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the Second Examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects.

Final Examination.—The Final Examination shall embrace the three divisions of—(1) the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy, and Pathology) and Clinical Medicine; (2) the Principles and Practice of Surgery (including Surgical Anatomy and Surgical Pathology) and Clinical Surgery; (3) Midwifery and Gynæcology, Medical Jurisprudence, and Hygiene (which divisions may be entered for separately at different times); and shall not take place before the termination of the full period of study. The fees for this Examination, payable not later than one week before the examination day, are as follows: For the whole Examination, taken at one time, in the case of candidates who have passed the First and Second Examinations, £15 15*s.*, of which £10 10*s.* shall be returned to unsuccessful candidates. For entering for each of the three divisions of subjects separately, £6 6*s.*, and on re-entry after rejection, £2 2*s.* in respect of each division or part thereof. This rule will also apply to any subsequent rejection. Any candidate admitted to the Final Examination, on the footing of having passed in the subjects of the First and Second Examinations at a recognised board, shall, on entering, pay the full fee of £26 5*s.*

All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c.

REGULATIONS FOR CANDIDATES WHO COMMENCED STUDY *after* JANUARY 1ST, 1892.

In addition to the courses above prescribed candidates are required to attend the following courses: Physics, three months; Elementary Biology, three months; Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; and twelve months' Hospital Practice with Clinical instruction.

The curriculum lasts for five years; the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries. Six months of the fifth year may be passed by the student as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as may be deemed satisfactory by the Committee of Management. The student's regularity of attendance in the wards and out-patient departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four Professional Examinations:

First Examination.—The First Examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, and (3) Elementary Biology. The fees payable for admission to the First Examination shall be for the whole Examination, £5; for each division separately, £2 10*s.*

Second Examination.—The Second Examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this Examination at the end of the second year of medical study. The fees payable for admission to the Second Examination shall be—for the whole Examination, £5.

Third Examination.—The Third Examination shall embrace Pathology and Materia Medica with Pharmacy. The fees payable for admission to the Third Examination shall be—for the whole Examination, £5; for re-entry in both subjects after rejection, £3.

Final Examination.—The Final Examination shall not be passed earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women and of New-born Children; and Medical Jurisprudence and Hygiene. All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface markings, &c. The fees payable for the Final Examination shall be,—for the whole Examination, £15, for re-entry in all subjects after rejection, £5.

There are six periods of Examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespective of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, Solicitor, 48, George-square; and the Registrar in Glasgow, Mr. A. Duncan, LL.D., 242, St. Vincent-street, to whom fees and certificates must be sent.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892.

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Two sets of Regulations are at present in force, under which examinations take place for the conjoint diploma of these bodies. The following Regulations are obligatory on all students commencing on or after Dec. 31st, 1891, the date already mentioned:—

PRELIMINARY EXAMINATION AND REGISTRATION.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence—(*a*) of having, before entering on medical studies, passed a Preliminary Examination in general education recognised by the General Medical Council; and (*b*) of having been registered by that

Digitized by Google

Council as a Student in Medicine. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of twenty-one years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.

Every candidate is required to pass four Professional Examinations—at the end of the first, second, fourth and fifth years of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body. All examinations shall be conducted as far as possible by demonstration of objects placed before the candidates.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; (2) of having been registered as a medical student by the General Medical Council; and (3) of having attended a course of—(*a*) Demonstrations and Dissections, (*b*) lectures on Theoretical Chemistry, winter courses; (*c*) Practical Chemistry, three months' summer or winter course; (*d*) Elementary Biology; (*e*) Physics. [*Note.*—Biology and Physics may be studied either before or after registration at institutions recognised for the purpose by the Colleges.] (*f*) Practical Pharmacy—(1) evidence of attendance for three months in the compounding department of a clinical hospital, which hospital shall have satisfied the committee of management that its means of instruction are sufficient, and shall return to the committee the names of its students at the commencement of the course, together with a record of their attendance at its close; or (2) evidence of attendance on a course of Practical Pharmacy in a recognised medical school, the course to consist of not less than twenty demonstrations; or (3) evidence of having served a full apprenticeship of three years, or of having acted as paid assistant for not less than one year, in the establishment of a Licentiate apothecary or of a registered pharmaceutical chemist. The fee for this examination is £15 15*s.*

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Practical Pharmacy. 3. Elementary Biology. 4. Anatomy—viz., Bones, with attachments of Muscles and Ligaments, and Joints. Candidates may take this examination as a whole at one time or in four parts, but no portion earlier than the end of the first winter session.

Second Professional Examination.—Candidates are not admissible to this examination before the end of their second winter session. Every candidate is required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination; also certificates of having attended—(1) a medico-chirurgical hospital for nine months; (2) Demonstrations and Dissections for six months; (3) Practical Histology for three months; (4) Lectures on (*a*) Anatomy for six months; (*b*) Physiology for six months; (*c*) Materia Medica for three months. Materia Medica may be deferred to the third year. The fee for this examination is £10 10*s.*

The subjects of the Second Professional Examination are the following:—1. Anatomy: the anatomy of the whole human body; (2) Histology; (3) Human Physiology; (4) Materia Medica. The candidate must present himself, in the first instance at least, in Anatomy and Histology; if he pass in either of these subjects he may, at the discretion of the examiners, get credit therefor. Physiology and Materia Medica may, at the option of the candidate, be passed at the end of the second or during the third year.

Third Professional Examination.—Candidates are not admitted to this examination before the end of their fourth winter session. Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination; also, in addition to the certificates required for the Second Professional Examination, certificates of having attended—(1) a medico-chirurgical hospital for eighteen months; (2) a midwifery hospital or maternity for six months, including evidence of having been present at thirty labours;[8] (3) clinical instruction in Mental Diseases at an institution recognised by the Colleges[8] for three months; (4) Operative Surgery, including operations on the Dead Subject, not less than thirty meetings of the class; (5) Demonstrations and Dissections, for six months; (6) Vaccination;[8] (7) Practical Pathology, not less than thirty meetings of the class; (8) Lectures on (*a*) Medicine for six months; (*b*) Surgery for six months; (*c*) Public Health and Forensic Medicine for three months; (*d*) Midwifery, including Diseases peculiar to Women and to New-born Children, for six months. Nos. 2, 3, and 6 may be deferred to fifth year. Satisfactory evidence must be produced of attendance in fever wards in connexion with the hospital attendance in either the third or a subsequent year. The fee for this examination is £9 9*s.*

The subjects for the Third Professional Examination are the following:—(1) Medicine; (2) Surgery; (3) Pathology; (4) Therapeutics; (5) Public Health and Forensic Medicine. A candidate must present himself, in the first instance at least, in Medicine, Surgery, and Pathology. Should he pass in either Medicine or Surgery he shall get credit therefor, even if he have failed in other parts of the examination.

Final Professional Examination.—Candidates are not admissible to this examination before the end of their fifth year of medical study. Every candidate is required before admission to produce evidence—(1) of having passed the Third Professional Examination; (2) of having attended—(*a*) Clinical Instruction in Ophthalmic and Aural Surgery for three months; (*b*) a midwifery hospital or maternity, if not taken in the fourth year, for six months; (*c*) Vaccination, if not taken in the third or fourth year; (*d*) Clinical Instruction in Mental Diseases, if not taken in the fourth year.

The subjects for the Fourth Professional Examination are the following:—(1) Medicine, including Medical Anatomy and Mental Diseases; (2) Surgery; (3) Operative Surgery and Surgical Anatomy; (4) Ophthalmic and Aural Surgery; (5) Midwifery, including Diseases of Women and New-born Children; and (6) the Theory and Practice of Vaccination. Every candidate shall produce evidence of having acted as medical clinical clerk and as surgical dresser. Candidates may present themselves for examination in *all* the subjects of the Final Examination at the *same* time, or in one or more of the following groups:—(*a*) In Medicine, including Mental Diseases, Medical Anatomy, and Clinical Medicine; (*b*) Surgery, including Ophthalmic and Aural Surgery, Clinical Surgery, Operations, and Surgical Anatomy; (*c*) Midwifery, including Diseases of Women and New-born Children, and the Theory and Practice of Vaccination. Candidates must pay the full fee before being admitted to any part of the examination. Candidates may take the groups in any order they please. The fee for this examination is £6 6*s.*

[8] May be taken in either the fourth or fifth year.

SOCIETY OF APOTHECARIES OF LONDON.

There are three examinations—Primary; Final, Section I.; and Final, Section II. The Primary Examination is held quarterly, on the first Wednesday and on the Monday and Thursday of the same week, in the months of January, April, July, and October. Final Examinations are held monthly.

The Primary Examination consists of two parts. Part I. includes Elementary Biology; Chemistry, the Principles of the Science which bear on the Study of Medicine; Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary Examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Section I. of the Final Examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy. Part II. includes the Principles and Practice of Medicine, together with Therapeutics, Pharmacology, and Prescriptions; Pathology and Morbid Histology; Forensic Medicine, Hygiene,

Digitized by Google

Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Part III. may be postponed to Section II. of the Final Examination, and candidates may enter for Parts I., II., and III. together or separately. Section I. of the Final Examination cannot be passed before the expiration of forty-five months after registration as medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society. Section II. of the Final Examination consists of two Parts. Part I. includes an Examination of and Written Report on Surgical Cases, and Operative Manipulation and Surgical Anatomy, Instruments and Appliances. Part II. includes an Examination of and Written Report on Medical Cases and Medical Anatomy. Section II. cannot be passed before the end of the fifth year.

The course of study for the Primary Examination is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, twelve months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School or at a place of instruction recognised by the Society. Evidence of having received instruction in the subjects of Part I. of the Primary Examination before registration as medical student will be accepted. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary.

The course of study for the Final, Section I., Examination includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of three winter and two summer sessions; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership,[10] six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship,[9] six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on twenty Midwifery cases. The course of medical study must extend over the above-mentioned period of forty-five months.

The course of study for the Final Examination Section II. includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of twelve months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. These courses must be taken at a general hospital recognised by the Society any time after the student has held the post of Dresser and Clinical Clerk. No candidate is eligible for the Final Examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. of the Final Examination the candidate must produce certificates: (1) of being twenty-one years of age; (2) of moral character; (3) of the course of medical study; and (4) of proficiency in vaccination signed by a teacher authorised by the Local Government Board. Candidates intending to present themselves for examination are required to give fourteen days notice. A form for this purpose will be sent on application.

[9] These offices must be held at a hospital, or other institution recognised by the society.

The fee for the three examinations is 15 guineas, or 5 guineas for each examination, except in the case of persons holding a foreign diploma, who are required to pay the entire fee of 15 guineas. The Secretary to the Examiners attends at the Hall of the Society, Blackfriars, E.C., from 10 to 12 o'clock daily.

UNIVERSITY OF BRUSSELS.

British and other practitioners holding registrable qualifications are admitted to the examination for the Doctorate of the University of Brussels without further curriculum. It is essentially a *practitioner's* examination and is separate from that intended for the Belgian students who take up the medical curriculum of the University. Candidates should appear with their diplomas at the Secretary's office not later than 2 P.M. on the day preceding the examination. The fees are—For matriculation, £8 12*s.*; for 1st Part, £4 8*s.*; for 2nd Part, £4 4*s.*; for 3rd Part, £4 8*s.*; for legalisation of diploma, 8*s.*—£22. Unsuccessful candidates may present themselves again three months after rejection. Candidates who have paid in advance the fees for the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; those who fail in the second recover the fees paid for the third examination. There are three examinations, viz.—1st Part: Medicine, Pathology, and Morbid Anatomy; General Therapeutics; Materia Medica and Pharmacology; Special Therapeutics and Mental Diseases. 2nd Part: Surgery; Midwifery; Hygiene; and Medical Jurisprudence. 3rd Part: Clinical Examination in Medicine at the Hospital; Clinical Surgical Examination; Examination in Midwifery, consisting of obstetrical operations on the mannequin (model of pelvis); Examination in Operative Surgery, consisting of some of the usual operations on the dead subject, such as Amputation, Ligature of an Artery, &c.; Regional Anatomy on the Dead Body, with Dissections; and Ophthalmology. Great importance is attached to practical knowledge, but candidates must also possess sound theoretical knowledge, the standard required varying with the subject. Pathological and other specimens are not usually shown. The examinations, which are entirely *viva voce*, take place on the first Tuesday in November, December, February, May, and June. Candidates have the option of passing each Part separately or of taking the three together, and the latter is the usual course. The time required for the three examinations seldom exceeds ten days, and is usually less. They are conducted in English. There are in England at present over 600 graduates holding this degree, and an English Association of Brussels Graduates has been formed.

Further information may be obtained from Dr. Walter Reeve, 38, Manchester-street, Manchester-square, W.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Consequent upon the issue of the Royal Warrant published in Army Orders dated July 1st, 1898, the Army Medical Staff and the Medical Staff Corps have been formed into the Royal Army Medical Corps. The Royal Warrant states the officers below the rank of Surgeon-Major-General serving in the Army Medical Staff shall be formed into a corps, together with the warrant officers, non-commissioned officers, and men of the Medical Staff Corps. Medical officers also have been placed, as regards sick leave of absence on full pay, on the same footing as those laid down for regimental officers. By a Royal Warrant, dated Nov. 10th, 1891, Art. 1208*b* of the Pay Warrant was revised by inserting the words "an officer of our Medical Staff" after the words "combatant officer," thus giving medical officers an equal title with combatant officers to reckon time on half-pay towards retirement, when the half-pay has been due to ill-health contracted in the performance of military duty. Under the Royal Warrant of July, 1895, time on half-pay not exceeding a year may under similar circumstances also reckon towards promotion. In the New Royal Warrant it is announced that the Queen has been pleased to approve of the following alterations in the ranks of the officers of the Royal Army Medical Corps:—

Old Ranks.	New Ranks.
Surgeon-Colonel	Colonel.
Brigade-Surgeon-Lieutenant-Colonel ... ... / Surgeon-Lieutenant-Colonel	Lieutenant Colonel.
Surgeon-Major	Major.
Surgeon-Captain	Captain.
Surgeon-Lieutenant...	Lieutenant.

Digitized by Google

The Warrant also states that the Medical Staff of the Army shall in future consist of Surgeon-Generals (ranking as Major-Generals), and the title of Surgeons-Major-Generals now serving shall be altered accordingly. Officers of the Royal Army Medical Corps holding appointments in the Household Troops are to be borne as seconded officers on the establishment of the Royal Army Medical Corps. The substantive rank of the Director-General of the Army Medical Service is that of Surgeon-General.

Admission into the Royal Army Medical Corps and Indian Medical Services is gained as the result of competitive examination. Under special conditions the admission may take place by nomination under the authority of the Secretary of State for War. Candidates for both services must, before being admitted to examination, possess a double qualification to practise Medicine and Surgery, and be registered under the Medical Act. They are also now required to produce certificates of having acted as a medical clinical clerk for six months, as surgical dresser for another six months, and of having had not less than three months' instruction at an ophthalmic hospital or the ophthalmic department of a general hospital, including a course on errors of refraction. They must also furnish satisfactory certificates of moral character. A candidate for the Royal Army Medical Corps must be between the ages of twenty-one and twenty eight, in good mental and bodily health, and must sign a declaration upon honour that he is of pure European descent; for the Indian Service a candidate must be between twenty-one and twenty-eight, of sound bodily health, and a natural-born subject of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. An entrance fee of £1 is required from each candidate admitted to the competition, and is payable at the conclusion of the candidate's physical examination, if he be pronounced fit. No candidate for the Indian Service will be allowed to compete on more than three occasions. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Surgery (1200 marks), Medicine, including Therapeutics and the Diseases of Women and Children (1200 marks), Anatomy and Physiology (600 marks), Chemistry and Pharmacy, and a practical knowledge of Drugs (600 marks). The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. By an Army Order dated May 1st, 1895, no candidate shall be considered eligible who shall not have obtained at least one-third of the marks obtainable in each of the compulsory subjects, and at least one-half of the aggregate of marks for all the compulsory subjects. The *voluntary* subjects are French (200 marks), German (200 marks), and Natural Sciences: (*a*) Physics (300 marks); (*b*) Zoology (300 marks); (*c*) Geology and Physical Geography (300 marks); and (*d*) Botany (300 marks); and for the Indian service Hindustani (200 marks). A candidate may not present himself for examination in more than two of the subjects included under the term "Natural Sciences." A number less than one-third of the marks obtainable in each of the voluntary subjects will not be allowed to count in favour of a candidate who has qualified in the compulsory subjects. Although the results of the examination in voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the list, which is determined by the numbers obtained under the two heads conjointly. It is understood that a scheme is now under consideration whereby the London examination will probably be modified in such a way that a good practical examination in Medicine and Surgery will secure a place on the list of successful candidates. It is hoped that a man who has held house appointments at hospitals will under the proposed scheme stand a better chance of securing a good place than the bookworm who has absorbed a smattering of the Natural Sciences and kept up his minute anatomy and physiology. After having passed this examination the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons-on-probation," receiving a daily pay of 8*s.* and certain allowances, to go through a four months' course of instruction in the special duties required of them in the services. The staff of the school consists of four professors, all of them men of high standing in their special departments. The Professorship of Military Medicine is held by Colonel K. Macleod, M.D., I.M.S. Colonel W. F. Stevenson, M.B., is Professor of Military Surgery; Colonel J. L. Notter, M.D., of Military Hygiene; and Dr. A. E. Wright, of Pathology. There is an Assistant Professor for each of these subjects who is an officer of the Royal Army Medical Corps. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, on board troopships and transports, recruiting, and other duties incident to military service. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad, the management of lunatics under the conditions of military service, &c. The course of six lectures on Lunacy and Military Asylum work is delivered at the Netley Lunatic Asylum by Lieutenant-Colonel Chester, M.B. The course of Hygiene comprises the examinations of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the consideration of the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The Pathological course includes bacteriology and demonstrations in physiological chemistry. The surgeons-on-probation are detailed for duty in the wards of the hospital, under the Professors and Assistant Professors of Medicine and Surgery. They spend two months in the medical and two months in the surgical division of the hospital, and there they are taught practically the details of the management of patients in a military hospital, the registration of their diseases, the duties of invaliding, the modes of filling up the regulation statistical returns and other service documents. The surgeons-on-probation are provided with quarters and are extra members of the mess at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list of those recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session eight prizes are awarded: the Herbert Prize of £20 to the surgeon-on-probation who has obtained the highest number of marks at the Netley examination; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in Hygiene; the de Chaumont prize of books to the one who takes second place in Hygiene; the Martin Memorial Gold Medal for the highest number of marks in the examination on Military Medicine; the Montefiore Medal and £21, awarded for Military Surgery; the Montefiore Second Prize, a revolver to the surgeon-on-probation who obtains the second highest number of marks in this branch; the Maclean prize of books for Clinical Medicine and Surgery and for Ward Work; and a prize of books for the highest number of marks gained in Pathology.

At the close of the Netley Session those surgeons-on-probation who have obtained one-third of the possible total of marks in each subject are recommended for commissions as Lieutenants. The Lieutenants of the British Medical Service pass on from Netley to Aldershot, where they go through a systematic course of instruction in company and ambulance drill and equitation. The officers of the Indian Medical Service do not go to Aldershot, but undergo, whilst at Netley, a course of instruction in company and ambulance drill and in other military duties. The position of the officers of the Indian Service on the list of Lieutenants is determined by the combined results of the London and Netley examinations, and, as far as the requirements of the service permit, they have the choice of commands in India—i.e., Bengal, Punjab, Madras, or Bombay—according to their position in that list. All officers appointed to the Indian Medical Service are now placed on one list. Though ordinarily employed within the limits of the command to which they are posted, they are liable for employment in any part of India. In the *Gazette* dated India Office, August 26 h, 1898, it is announced that Her Majesty has deemed it expedient to alter the ranks of

Digitized by Google

the officers of the Indian Medical Service, The same military titles as those conferred on the officers of the Royal Army Medical Corps are announced for the officers of the Indian Medical Service.

The Royal Army Medical Corps.—Lieutenants, if duly recommended, are promoted to be Captains on completing three years' full-pay service.

Captains, if recommended by the Director-General, are promoted to be Majors on completing twelve years' full-pay service, of which three must have been passed abroad. Before being promoted they will be required to pass an examination. This examination may be taken at any time after their seventh year of service. It will embrace the following subjects: (*a*) Surgery and Surgical Anatomy; (*b*) Medicine and Pathology; and (*c*) Hygiene, within the limits treated of in "Notter and Firth's Practical Hygiene," also the regulations regarding the sanitation of garrisons, quarters, hospitals, &c., as well as of camps and hospitals in the field, and of transports, troop and hospital ships; (*d*) duties of medical officers at home and abroad and at sea, as defined in the regulations, also hospital organisation and administration in peace and war, including the transport of sick and wounded by land and sea; (*e*) and the administration, interior economy, command, and discipline of the Royal Army Medical Corps, together with a knowledge of the principles of military law and their practical application (a certificate of proficiency in military law obtained at a garrison class will exempt the holder from examination in the latter).

A certificate will be required from a recognised teacher of surgery in any medical school, at home or abroad, in which operative surgery is taught, showing that the officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator.

A report on any subject of a practical professional character, to be selected by the officer himself, and certified to be his own composition and in his own handwriting, will also be required. Considerable importance will be attached to the literary and scientific merits of this report, which must be furnished before the officer completes twelve years' service.

The examinations will be conducted by printed questions, which will enter so far into the subject matter of each head selected for examination as to show that the officer's knowledge has been fully tested.

The questions and answers will be forwarded, under a sealed confidential cover, to the Director-General for transmission to the examiners, who will report to the Director-General as to the competence of the officer examined.

The examination in Medicine and Surgery will be held by two gentlemen appointed by the Secretary of State; that in Hygiene by the Professor of Hygiene, Army Medical School, Netley; and that in Regulations, Duties, Military Law, &c., by an administrative medical officer, nominated for the purpose by the Director-General.

Any higher qualification, such as M.D., F.R.C.S., &c., or any diploma in Hygiene and State Medicine, taken after May 1st, 1890, will not exempt Captains from this examination.

Majors are, if duly recommended, promoted to be Lieutenant-Colonels on completing twenty years' full-pay service.

The selection of Lieutenant-Colonels for advancement to the grade of Colonel is made on the grounds of ability and merit (on the recommendation of the Commander-in-Chief), in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military officers under whom he may have served, as set forth in their Annual Confidential reports. He must be physically fit for general service and have served abroad for at least eight years.

A Lieutenant-Colonel, to be eligible for selection as Colonel, must have served abroad at least ten years, of which three must have been in India. All promotions from the rank of Lieutenant-Colonel to that of Colonel, and from the rank of Colonel to that of Surgeon-General, shall be given for ability and merit, upon the selection of the Commander-in-Chief, with the approval of the Secretary of State, and the grounds of such selection shall be stated in writing. In all such cases the amount of service abroad shall be expressly stated. All officers under the rank of Colonel are placed on the retired list at the age of fifty-five, and those of that rank and of the rank of Surgeon-General at the age of sixty, except that in any particular case in which it may be considered necessary for the interest of the public service the age of retirement of a Surgeon-General may be extended for a period not exceeding two years. From recent promotions which have been made it is evident that Colonels who have passed the age of fifty-seven before being selected for the rank of Surgeon-General will be passed over in favour of younger officers who can, by reason of age, serve a full three years in the rank of Surgeon General.

Foreign Service.—Army Order 85 of June, 1897, states that the periods of service abroad, reckoning from the date of embarkation at home, will (except in the case of a Surgeon-General or Colonel) be five years for all stations abroad (except that on the west coast of Africa), unless such period should be incompatible with the interests of the public service.

Sick Leave.—An officer of the Royal Army Medical Corps may be allowed full pay during sick leave of absence on the same conditions as those laid down for regimental officers.

Service on the West Coast of Africa.—Officers who entered the Royal Army Medical Corps, or volunteered expressly for service on the West Coast of Africa on or after the 1st of March, 1873, receive double pay while actually serving on the coast. Candidates who present themselves expressly for service in the Royal Army Medical Corps on the West Coast enter under the same qualifications as other candidates, except that they may be admitted up to thirty years of age. After 3 years' actual service on the coast they are eligible for general service. If, however, it be certified by a medical board that any such officer is unfit for further duty on the coast he shall be eligible for general service, though he may not have completed 3 years' service there. For each year's service on the coast an officer is entitled to a year's leave at home. Each year or portion of a year served on the West Coast reckons double towards voluntary retirement or retired pay, provided that an officer has served 12 months on the coast.

Indian Medical Service.—Officers on appointment are, when possible, provided with passage to India by troopship; when troopship accommodation is not available passage at the public expense is provided by steamer, or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2*s.* a day. This payment does not include the cost of liquors, which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of leaving Netley will be considered as having forfeited his appointment, unless special circumstances shall justify a departure from this regulation. Lieutenants are promoted to the rank of Captain on completing three years' full-pay service, Captains to the rank of Major after twelve years' service, and Majors to the rank of Lieutenant-Colonel after twenty years' service. No examination to qualify for promotion is required. All promotions to higher grades are to be given by selection for ability and merit. In case of distinguished service in the field a medical officer may be at once promoted from any rank to the one next above it. The ages for compulsory retirement are the same as those for the Royal Army Medical Corps. Officers of the Indian Medical Service below the rank of Colonel may be granted: 1. Privilege leave under such regulations as may from time to time be in force. 2. Leave out of India for no longer period than one year, capable of extension to two years' absence from duty, on the following pay:—After arrival in India, on first appointment, £200 a year; after the commencement of the fifth year's service for pension, £250 a year; after the commencement of the tenth year's service for pension, £300 a year; after the commencement of the fifteenth year's service for pension, £400 a year; after the commencement of the twentieth year's service for pension, £450 a year; and after the commencement of the twenty-fifth year's service for pension, £500 a year. 3. Leave in India, but for the period of one year only, on full military pay and half the staff salary of appointment. No extension of leave involving absence from duty for more than two years, whether taken in or out of India, can be granted except on specially urgent grounds and without pay. An officer unable on account of the state of his health to return to duty within the maximum period of two years' absence, unless he is specially granted an extension of leave without pay, is placed on temporary half-pay or the retired list, as the circumstances of the case

Digitized by Google

may require. An officer is also liable to be placed on half-pay or the retired list should his health require an undue amount of leave, whether in or out of India. Leave may be granted at any time, but solely at the discretion of the Commanders-in-Chief or of the Local Governments in India in the case of officers not under the direct orders of a Commander-in-Chief. Officers of the Administrative grades may be granted one period of leave not exceeding eight months during their tenure of appointment.

Naval Medical Service.—A candidate must be between the ages of twenty-one and twenty-eight, and must be the son of parents of pure European blood. He must declare his readiness for general service at home or abroad. Candidates will be examined by the Board in the following compulsory subjects: (*a*) Medicine, including Therapeutics and Diseases of Women and Children, 1200 marks; (*b*) Surgery, 1200 marks; (*c*) Anatomy and Physiology, 600 marks; and (*d*) Chemistry and Materia Medica, 600 marks. No candidate is considered eligible who does not obtain one-third of the maximum marks in each of the compulsory subjects. Candidates may be examined in the following voluntary subjects: Zoology, 300 marks; Botany, 300 marks; Physics, 300 marks; Geology and Physical Geography, 300 marks (no candidate will be allowed to present himself for examination in more than two of these subjects); French and German (200 each), 400 marks. A number less than one-third of the marks obtainable in each of these voluntary subjects will not be allowed to count in favour of a candidate who has qualified in the compulsory subjects. Successful candidates immediately after passing the examination will receive commissions as surgeons in the Royal Navy and will undergo a course of practical instruction in Naval Hygiene, &c., at Haslar Hospital. Surgeons are promoted to be Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination after completion of eight years' service from the date of entry; and Staff Surgeons to Fleet Surgeons after twenty years' service if recommended by the Director-General. Deputy-Inspectors-General are promoted by selection for ability and merit from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign service, or four years' mixed, of which not less than two must have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty (except that if in any particular case the Lords Commissioners of the Admiralty may consider that the interests of the public service will be materially advanced by the further retention of an Inspector-General on the active list, the age for retirement of such Inspector-General may be extended to sixty-two) and other grades at fifty-five years of age, and all ranks at any time if an officer has not served for five years. In calculating service for retired pay time on half-pay will be taken as equivalent to one-third service on full-pay. All retired officers are liable, till the age of fifty-five, to serve in time of declared national emergency in a rank not lower than that held on retirement.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service:—

ARMY.

Rank.	*Rates of Pay.*	*Gratuities.*	*With the Rank of*
	Daily.		
Surgeon on probation ..	£0 8 0	—	—

Colonel	2 0 0	1 15 0	Colonel
Surgeon-General	2 15 0	2 0 0	Major-General

Director-General of the Army Medical Service, £1500 yearly; retired pay from £1125 to £830, according to length of service as Director General.

Under Army Order 63 of May, 1897, officers of the Royal Army Medical Corps attached to a militia unit during preliminary drill and training are entitled to an allowance in aid of mess at the rate of 4*s.* a day.

* Applies equally to Lieutenant-Colonels, Majors, Captains, or Lieutenants, according to periods of service—i.e., ten, fifteen, or eighteen years.

An officer who, on voluntary retirement, has served for less than three years in the rank from which he retires is only entitled to the gratuity or retired pay assigned to the next lower rank.

† Half-pay is also applicable to officers having less than twenty years' service, as follows:—

Lieut.-Col., Major, Capt., or Lieut.:

	Daily.
Under 5 years' service	£0 6 0
After 5 ,, ,, ...	0 8 0
After 10 ,, ,, ...	0 10 0

4 ,,	..	1 9		2 0 0
Inspector-General	2 15 0	1 18		

The half-pay, retired pay, and gratuities on retirement are liable to reduction in cases of misconduct.

The hospital allowances for Medical Officers at home and abroad in lieu of provisions for themselves and servants and for fuel and light, are as follows:—

Rank.	At home.	Abroad.
	£	£
Inspector-Generals of Hospitals	85	130
Deputy Inspector-Generals	67	112
Fleet Surgeons and Staff Surgeons	53	112
Surgeons	39	108

Medical officers serving afloat receive an allowance of 1*s.* 6*d.* a day in lieu of provisions, fuel, and lights, as laid down in the Queen's Regulations.

The allowance of 5*s.* a day, in addition to full pay, at present granted to the Fleet Surgeon of a flag-ship bearing the flag of a Commander-in-Chief on a foreign station, will be given to the senior medical officer of such ship, being a Fleet or Staff Surgeon; and an allowance of 2*s.* 6*d.* a day to the senior medical officer, being a Fleet or Staff Surgeon, of the ship of a Commodore or of a senior officer commanding a foreign station.

Candidates will do well to notice that the regulations issued to applicants do not put any limit on the amount of half-pay service which they may be compelled to undergo.

‡ If the health of a surgeon breaks down before he completes eight years' service, even if his disability be contracted in the service or be due to climatic causes, he is liable to be at once placed on the retired list, receiving a gratuity at the rate of £125 for each year of completed service.

INDIAN MEDICAL SERVICE.§

The rate of pay drawn by Lieutenants from the date of passing the final examination at the Army Medical School until arrival in India is 10*s.* a day.

Pay at the above rate is issued in this country up to the date of

Digitized by Google

embarkation, and an advance of two months' pay at the same rate is also made prior to embarkation, which is adjusted in India.

The following are the rates of "Indian pay and allowances" which will be drawn by officers hereafter appointed to the Indian Medical Service:—

Rank.	Years' service.	Indian pay and allowance per mensem. When not holding an appointment carrying higher pay. Rs. a. p.	A. When not receiving any staff allowance. Rs. a. p.	B. When receiving staff allowance in addition. Rs. a. p.
Lieutenant-Colonel (Senior)		900 0 0		
Lieutenant-Colonel	25 and over	888 12 0		
Lieutenant-Colonel	20 ,,	852 8 7		
Major	15 ,,	677 6 11		
,,	12 ,,	640 14 6		
Captain	10 ,,		500 0 0	450 0 0
,,	5 ,,		450 0 0	400 0 0
Captain and Lieutenant	under 5		350 0 0	300 0 0

On first appointment they will only come into receipt of "Indian pay and allowances" from the date of their arrival in India.

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries:—

	Rs. per mensem.
Surgeon-General	2700 to 2200
Colonel ... from	2250
Colonel ... to	1800
Lieutenant-Colonel in substantive charge of a native regiment	1000 with Rs. 90 horse allowance in cavalry regiments.
Major in substantive charge of ditto	800 with Rs. 90 ditto.
Captain above 5 years' full-pay service in substantive charge of a native regiment	600 with Rs. 60 ditto.
Captain or Lieutenant under 5 years' ditto in substantive charge of a native regiment	450 with Rs. 60 ditto.

The salaries of other substantive medical appointments in the Civil and Military Departments are consolidated and vary from Rs. 1800 to Rs. 400 per mensem.

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department. The salaries of these appointments are from Rs. 600 to Rs. 2250 per mensem.

Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment.

RETIRING PENSIONS AND HALF-PAY.

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension, on completion of the required periods of service:—

After 30 years' service for pension	£700 per annum + £350 after 5 years' active employment in India as a Surgeon-General, or + £250 per annum after 5 years' active employment as a Colonel.
,, 25 ,, ,, ,,	£500 per annum.
,, 20 ,, ,, ,,	£365 ,,
,, 17 ,, ,, ,,	£292 ,,

Officers not entitled to pension, when placed on temporary or permanent half-pay will be granted the British rate of half-pay of their military rank, as under:—

Rank.	Rates of Half-pay. ‖ Per diem. s. d.	Per annum. £ s. d.
Lieutenant-Colonel (Senior)	11 0	200 15 0
Lieutenant-Colonel		
Major	6	173 7 6
Captain	7 0	127 15 0
Lieutenant	8 0	54 15 0

INVALID PENSIONS.

An officer who has become incapacitated for further service in India on account of unfitness caused by duty may, after he has been two years on temporary half pay, be granted an Invalid Pension on the following scale:—

	Per annum.
After 16 years' pension service	£272
,, 15 ,, ,, ,,	252
,, 14 ,, ,, ,,	232
,, 13 ,, ,, ,,	212
,, 12 ,, ,, ,,	192

§ No staff or regimental allowance can be drawn until the lower standard examination in Hindustani has been passed. As many lieutenants have been sent to the frontier immediately on arriving in India, they have found it impossible to study and pass this examination, and have consequently been doing regimental and other work for Rs. 350 a month. Lately a concession has been granted to medical officers so situated on the frontier, but the rule is still most illiberal and requires alteration.

‖ Officers cannot retire *in India* on half-pay (No. 45, Feb. 28th, 1865).

WOUND PENSIONS.

Officers are entitled to the same allowances on account of wounds and injuries received in action as are granted to combatant officers of Her Majesty's Indian Military Forces holding the corresponding military rank.

FAMILY PENSIONS.

The claims to pension of widows and families of officers are treated under the provisions of such Royal Warrant regulating the grant of pensions to the widows and families of British officers as may be in force at the time being.

The widows and families of officers are also entitled to pensions under the Indian Service Family Pension Regulations, for the benefits of which all officers must, as a condition of their appointment, subscribe from the date of their arrival in India.

METROPOLITAN MEDICAL SCHOOLS.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a service of 744 beds, of which 674 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. Ten house physicians and ten house surgeons are appointed annually. During their first six months of office they act as "junior" house physicians and house surgeons and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Two assistant electricians are appointed every six months. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the diligent students. All the appointments are now free.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pathology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

A recreation ground of ten acres has been purchased by the school committee at Winchmore-hill for the use of the Students' Amalgamated Clubs, and all students are expected to become members.

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, 110 guineas if paid in a single sum on entry, or 121 guineas if paid in five instalments; the sons of Registered Medical Practitioners pay 100 guineas in one sum or 110 guineas in five sums; for Dental students, 54 guineas, or 60 guineas in two equal instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, Huxley, and Pereira Prizes.

Classes for the Preliminary Scientific Examination of the University of London are held at this Medical School. The fee for the whole course, which begins in October, is

[1] For Scholarships see p. 638 et seq.

Digitized by Google

15 guineas. There are also special classes for the practical work for the Department of Public Health and a course in the subject of diseases of tropical climates.

A recreation ground has recently been presented to the Students' Club by Mr. E. J. Churchill.

ST. GEORGE'S HOSPITAL.—Students may become Perpetual Pupils by payment of £150 on entering, or of £160 in four annual instalments. Perpetual pupils are entitled to perpetual admission to lectures and demonstrations as well as to the entire medical and surgical practice of the hospital; they may compete for all prizes and exhibitions, may become clinical clerks during six months and dressers during another six months, or longer if required, without fee, may attend midwifery practice, and may compete for all hospital and school appointments without extra charge. Four house surgeoncies and four house physiciancies, and the salaried offices of obstetric assistant, senior and junior anæsthetists, medical registrars (2), surgical registrar, curator and assistant curator of the Museum, besides demonstratorships and a number of junior hospital appointments, are open to perpetual pupils. Students not being perpetual pupils are admitted to lectures, demonstrations, and hospital practice on payment of £50 annually for two years and £20 annually for succeeding years. Such students may become Perpetual in their third year if they wish and if their conduct has been satisfactory.

GUY'S HOSPITAL.—House physicians, house surgeons, assistant house physicians, and assistant house surgeons, obstetric residents, gynæcological assistants, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical ward clerks, clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical staff, according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physicians, who hold office for three months, attend in the out-patient department four afternoons in the week, and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards, and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each, and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons. The surgeons' dressers are selected from those students who have completed their third winter session, and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, two in number, are provided with board and lodging in the college free of expense.

Higher Examinations.—Classes are held throughout the year for the Preliminary Scientific Examination of the University of London; and special courses of instruction in anatomy and physiology are provided for students preparing for the Primary Fellowship examination and the intermediate M.B. examinations of Oxford, Cambridge and London. Two courses of Laboratory instruction for candidates for a Diploma in Public Health are given annually.

The College.—The College stands upon a site fronting the east gate of the hospital, and is connected with it by a subway. The building serves as a Residential College for Students, and at the same time provides accommodation for the Students' Club. The Clubs' Union ground is less than twenty-five minutes' journey from the Hospital. The new school buildings are now open.

KING'S COLLEGE.—Resident medical officers have rooms at the hospital and commons free; they are selected by examination and hold their appointment for six months. There are two physician's assistants, two physician accoucheur assistants, and three house surgeons. Sambrooke registrarships, value £50 per annum, are tenable for two years. Clinical assistants senior and junior of the special departments—ophthalmic, ear, and throat. Senior dressers and dressers, clinical clerks, assistant demonstrators of anatomy and physiology, and prosectors are re-elected by examination, and in consideration of their former work in the medical school as matriculated students. Classes for the science subjects required by the University of London are held by the Professors of the Science Faculty of King's College, and students avail themselves of their laboratories.

Laboratories.—Bacteriology, State Medicine, Pathology, and Neuropathology have special laboratories.

Resident Chambers.—There are chambers at King's College available for a limited number of students; rent, including dinner during terms, £50 to £60 a year.

Athletic Club.—All students are entitled to the privileges of the Athletic Club, which manages a large recreation ground of the College at Wormwood Scrubbs.

LONDON HOSPITAL AND COLLEGE.—The hospital has nearly 800 beds in constant use, and no beds are closed. Being the only general hospital for East London—i.e., for a million and a half people—the practice is immense. In-patients last year 11,146; out-patients, 161,033; accidents, 14,781; major operations, 2320. Owing to the enormous number of patients more appointments are open to students than at any other hospital. Receiving-room officers, house physicians, house surgeons, &c.: sixty of these qualified appointments are made annually and more than 150 dressers, clinical clerks, &c., appointed every three months. All are free to students of the college. Holders of resident appointments have free board. Twenty-seven scholarships and prizes are given annually. Five entrance scholarships are offered in September. Special classes are held for the University of London and other higher examinations. Special entries for medical and surgical practice can be made. Qualified practitioners will find excellent opportunities for studying the rarest diseases. Lectures and classes are held throughout the year to suit the requirements of candidates desirous of obtaining the diploma in Public Health. These courses are recognised both by the University of Cambridge and by the Examining Board in England. A reduction of 15 guineas is made to the sons of members of the profession. New laboratories and class-rooms for Bacteriology, Public Health, Operative Surgery, Chemistry, Biology, &c., will be completed by Oct. 1st. The Clubs Union Athletic Ground is within easy reach of the hospital. The Metropolitan and other railways have stations close to the hospital and the college.

ST. MARY'S HOSPITAL.—There are three house physicians and three house surgeons, each appointed for six months, and two obstetric officers, each appointed for six months. They board free of expense in the hospital, except that the obstetric officer resides outside the hospital for the first three months. These appointments are awarded after competition, without additional fee. Two demonstrators of anatomy are appointed annually, with a salary of £70 each; and a demonstrator of physiology, at £100 a year. All these officers are eligible for re-election. Two prosectors of anatomy, two or more assistant demonstrators of anatomy, biology and pathology are appointed annually, and receive an honorarium of £5 each. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. The hospital contains 281 beds. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases. There is an out-patient department for Diseases of Children. Special assistance is given to intending candidates for the final examinations of the Medical, Surgical, and Obstetric tutors.

Clarence Memorial Wing.—The foundation-stone of this important addition to the hospital was laid by H.R.H. the Prince of Wales and the new out-patient department in it is now open. The old out-patients' rooms have been given up to the school to make additional class-rooms, with a new museum, a new physiological theatre, and pathological and bacteriological laboratories. The new wing will present features of the greatest interest in the bearing it must necessarily have upon the future efficiency of the Medical School. The Lying-in Wards will be more especially noteworthy as the first-established within a metropolitan general

FEES for School and Hospital Medical and Surgical Practice.	£135, or in four instalments: 1st year, £56; 2nd year, £40; 3rd year, £30; 4th year, £10.		

hospital. The prospectus may be had on application to Mr. F. H. Madden, the School Secretary, to Mr. G. P. Field, the Dean, or Dr. A. P. Luff, the Sub-Dean.

A residence for students, 33 and 35, Westbourne-terrace, W., in connexion with the hospital, is under the charge of a warden, Mr. H. S. Collier, F.R.C.S., who is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: £75 for the academical year.

Qualified medical men are admitted to attendance on hospital practice according to a conjoint scheme with other hospitals. Particulars may be had on application.

MIDDLESEX HOSPITAL.—The hospital contains 320 beds. There is a special department for patients suffering from cancer, consisting of four wards, containing thirty-four beds; here cancer patients are received and attended for a period limited only by the duration of their disease.

Hospital Appointments.—Clinical Clerkships and Dresserships in all departments are allotted to students without any extra fee. Eighteen Resident Appointments are annually filled from the pupils of the hospital, each appointment extending over six months.

The Curriculum is designed to meet the requirements of the Royal Colleges of Physicians and Surgeons and of the Universities of London, Cambridge, &c. Special Classes are held to prepare students for the Preliminary Scientific M.B. (Lond.) Examination and for the Primary Examination for the diploma of F.R.C.S. Eng.

The new school buildings to be opened next session will provide a much larger dissecting-room, a room for operative surgery, a complete physiological department, spacious pathological and bacteriological laboratories, and extended facilities for the teaching of Chemistry, Physics, Biology, &c.

A Residential College to accommodate about thirty students adjoins the hospital. The charge for residence is £10 10*s.* and £8 8*s.* per term, according to the position of the room. Breakfast, luncheon, and dinner are supplied in the College Hall at a very moderate charge.

Fees.—The Composition Fee for the entire curriculum is 120 guineas, or 130 guineas if paid in three instalments. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students who have completed the study of Anatomy and Physiology or passed the London Preliminary Scientific M.B. Examination are received on special terms.

ST. THOMAS'S HOSPITAL.—The composition fee to Hospital Practice and Lectures may be paid in the following ways:—1. £150 on entrance in one sum. 2. £157 10*s.* in instalments: (*a*) by two payments, £85 on entrance and £72 10*s.* at the beginning of the second year; (*b*) by three payments, £75 at the beginning of the first year, £50 at the beginning of the second year, and £32 10*s.* at the beginning of the third year; and (*c*) by four payments, £65 at the beginning of the first year, £50 at the beginning of the second year, £30 at the beginning of the third year, and £12 10*s.* at the beginning of the fourth year. Gentlemen entering at St. Thomas's for Lectures and Hospital Practice of the second and subsequent years pay £130 on entrance, or three instalments of £52 10*s.*, £42, and £42. Students entering for Lectures and Hospital Practice of third and subsequent years pay a composition fee of £80, or £52 10*s.* on entrance and £31 10*s.* one year subsequently. The fee for attendance on the general subjects required of students in Dental Surgery is for the two years £65, or, by instalments, £55 for the first year and £15 for the second year. If certificates for Dental Practice are also required the special fee for that subject has to be paid. Qualified practitioners are admitted by a joint ticket to the practice of nine hospitals on terms which may be ascertained from the medical secretary.

UNIVERSITY COLLEGE, LONDON.—*Composition fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 135 guineas, if paid in one sum at the commencement of the course; 140 guineas if paid by instalments, as follows—first year, 65 guineas; second year, 50 guineas; third year, 25 guineas. 2. For those students who do not require to attend Chemistry, Pharmacy, and Elementary Biology at a medical school (under the regulations of the Examining Board in England) the fee will be—117 guineas, if paid in one sum; 122 guineas, if paid by instalments, as follows—first year, 55 guineas; second year, 40 guineas; third year, 27 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 55 guineas (paid in one sum). 4. For the course of instruction for the Final M.B. Examination of the University of London, 76 guineas, if paid in one sum; 78 guineas, if paid by instalments, as follows—first year, 45 guineas; second year, 33 guineas. 5. Composition fee for Dental Students, 65 guineas. 6. Composition fee for the whole course of instruction for the Preliminary Scientific (M B.) Examination of the University of London, 35 guineas.

Eight house physicians, six house surgeons, four senior and

Digitized by Google

eight junior obstetric assistants are selected annually by examination from among the senior students. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, receiving free board and lodging.

Several professors and other gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons unconnected with the College who receive boarders into their families; among these are several medical gentlemen and clergymen.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædics, and for Diseases of Women, and a special ward for Children. The Anatomical Museum is open to the students. There are also Pathological and Materia Medica Museums.

A curator of the museum and a pathologist, with salaries of £40 and £50 respectively, and a medical and surgical registrar, each with a salary of £40, are appointed annually. Two house physicians, two house surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons; also two assistant house surgeons with commons only. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

Preliminary Scientific.—Special classes are held in the subjects of this examination—Chemistry, Dr. Hake; Physics, Mr. Somerville; Biology, Dr. Tims. The extra fee to a general student is 12 guineas.

Intermediate M.B.—Advanced Physiology and Histology, Dr. Gossage; Advanced Anatomy, Mr. Tubby; Organic Chemistry, Dr. Hake; Materia Medica, Dr. Murrell.

D.P.H.—The course of Laboratory Instruction may now be taken. Physics, Mr. Somerville; Chemistry, Dr. Hake; Bacteriology, Dr. Blaxall. Fee 12 guineas.

Bacteriology.—A course in General Bacteriology is given by Dr. Blaxall. Fee £5 5*s*.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 30, Handel-street, Brunswick-square, W.C.—The winter session of this School will begin on Oct. 3rd, 1898, and will end on March 31st, 1899. The summer session will begin on May 1st, and will end on July 30th, 1899. No student will be admitted to the study of Medicine who has not completed her eighteenth year. The admission of students rests exclusively with the Executive Council. The opening address will be given on Tuesday, Oct. 4th, by Dr. J. Walter Carr, senior physician to out-patients, Royal Free Hospital, at 8 P.M. The prizes will be given on the same evening by Mrs. Charles Burt.

In addition to the list of Scholarships tabulated in another column three Evans Prizes of £3 3*s*., £2 2*s*., and £1 1*s*. are given in the Midwifery Class to enable students to take operative midwifery. Two Durham Prizes, value £5 and £3, are given on the results of the class examination in gynæcology. There is also a small fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help to obtain additional experience in operative midwifery, &c. The Evans Prize for Operative Midwifery, value £5 5*s*., will be offered at the end of the winter session, 1899. Two Singleton prizes are offered to students of the School who have held posts at the New Hospital for Women. Honoraria from the Royce Memorial Fund are given to the senior assistant anæsthetist at the Royal Free Hospital. Prizes and Certificates of Honour are awarded in each class at the end of the session. Secretary, Miss Douie, M.B., M.A.

A new block of buildings, opened on July 11th by the H.R.H. the Princess of Wales, has been added to the school, comprising large and well-equipped laboratories for chemistry, physiology, and anatomy. A second block is now in course of erection and will comprise three lecture theatres and a biological laboratory. The teaching of the school has been extended in several departments. More attention is now given to the subject of pathology and extra lectures and practical demonstrations have been added to the course. Dr. Andrewes has been appointed lecturer. A special class in Practical Toxicology is held in October in preparation for the M.B. Lond. examination. Dr. Patrick Manson has been elected lecturer on Tropical Medicine and a course of lectures on this subject will be given during the summer session.

COOKE'S SCHOOL OF ANATOMY.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year; that is to say that it does not receive more curriculum students than can each be supplied in the course of his studies with three entire "subjects."[1] Corresponding advantages are offered in regard to the physiology. The charges are but slightly in excess of current charges. The Bland Sutton Presentation, named after Mr. Bland Sutton, F.R.C.S., Sir Erasmus Wilson Lecturer at the Royal College of Surgeons, Surgeon to the Middlesex Hospital, &c. (a former pupil of the school), is intended to meet the case of specially earnest and deserving men of limited means. It confers the privilege of free medical education during the first two years of medical studies. Particulars will be forwarded on application. Gentlemen rejected at their Anatomical and Physiological Examinations (Second Conjoint, &c.) can get "signed up" from this school for the three or six months' supplementary work they are now required to put in before re-examination. This school is also intended to meet the requirements of qualified practitioners wishing to obtain some of the higher qualifications, and is recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The school possesses a good collection of physiological apparatus. The operations of surgery are performed by the students on the dead body.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

BETHLEM HOSPITAL.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, and will be provided with such apartments, complete board, attendance, and washing, as the Committee shall consider reasonable. They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Lectures are also given in connexion with the London Post-graduate Course.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1*s*. for one month; three months, £2 2*s*.; perpetual, £5 5*s*. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The next course will commence in October. Clinical Assistants are appointed to the Assistant Physician in the out-patient department and Clinical Clerks to the Physician in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—During the past year 689 in-patients have been admitted, and the large number of 31,221 cases have been treated since the opening of the wards in 1855. The number of out-patients treated during 1897 was 16,994, and 585,038 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to the Secretary of the Clinical Sub-committee at the hospital. Consulting Physicians: Dr. E. L. Birkett and Dr. J. C. Thorowgood. Consulting Surgeon: The Rt. Hon. Lord Lister. P.R.S. Physicians: Drs. Eustace Smith, G. A. Heron, Vincent D. Harris, E. Clifford Beale, Harrington Sainsbury, and T. Glover Lyon. Surgeon: Mr.

[1] The evidence given before the Parliamentary Committee which led to the passing of the Anatomy Act, was to the effect that three entire "subjects" ought to be considered the minimum that should be allotted to each medical student during the course of his studies.

J. F. C. H. Macready, F.R.C.S. Assistant Physicians: Sir Hugh R. Beevor, Bart., and Drs. W. J. Hadley, E. H. Colbeck, Arnold Chaplin, Hugh Walsham, and J. J. Perkins.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's-inn-road.—The hospital contains accommodation for seventeen in-patients, and has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 7500 out-patients and 300 in-patients were treated. Fee for three months' attendance, 3 guineas; for six months, 5 guineas. A course of lectures on the special diseases treated at this hospital is delivered during the winter and summer months by members of the staff. As an evidence of the interest excited by these lectures, it may be mentioned that last year there were over a thousand attendances at the series with an average of eighty at each lecture. The date of these lectures is announced in the medical journals prior to their commencement. They are free to qualified practitioners and advanced students of medicine. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages, for which a special department has been inaugurated. Consulting Surgeon: Mr. Thomas Nunn. Surgeons: Mr. Lennox Browne, Dr. Arthur Orwin, Dr. Dundas Grant, and Dr. Percy Jakins. Assistant Surgeons: Mr. Wyatt Wingrave Dr. Holloway, and Mr. Heath. Bacteriologist: Mr. St. George Reid. Dental Surgeon: Mr. George Wallis. Defects of Speech: Mr. William Van Praagh. Registrar: Mr. Nourse. In addition the following appointments are open to qualified members of the profession:—Three Assistant Registrars and Anæsthetists, tenable for twelve months; and twelve Clinical Assistants, tenable for six months. Secretary: Mr. Richard Kershaw.

HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with this institution there has been for some years a well-organised Clinical Department. This has been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their fourth year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large number of out-patients affords exceptional opportunities for practical instruction in the use of gynæcological instruments and for the study of diseases peculiar to women. Clinical instruction is also given in the theatre and the wards. Fee for the three months' course, £8 8s. Any further information can be obtained by letter addressed to the Dean at the hospital.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (Established 1814.)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients. Expenditure for 1897, £7675; income (including legacies, £900), £6176. The attendance of out-patients averages 24,000 annually.

ROYAL EAR HOSPITAL, Soho. (Founded 1816.)—Courses of six weeks' duration in Diseases of the Ear and Nose are given by the members of the staff throughout the teaching year. Students can attend one or more surgeons, the fee for each surgeon's course being one guinea. The teaching is of a practical character, and the number of students is limited. The next series of classes will commence on Oct. 3rd. For information address the Hon. Sec. of the Medical Board.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Consulting Physician: Sir S. Wilks, Bart., President of the Royal College of Physicians of London. Consulting Surgeon: Mr. W. Adams. Physicians: Drs. R. Burnet, E. C. Beale, C. E. Beevor, H. W. Syers, James Galloway, and A. Morison. Obstetric Physician: Dr. Blacker. Surgeons: Messrs. J. Macready, C. B. Lockwood, H. Allingham, P. T. B. Beale, and G. B. M. White. Ophthalmic Surgeon: Mr. A. S. Morton. Ear, Throat, and Nose Surgeon: Mr. W. R. H. Stewart. Skin Department: Dr. Whitfield. Dental Surgeon: Mr. P. Traer Harris. This hospital is now recognised by the Examining Board in England by the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the Medical Curriculum. The hospital contains 155 beds, of which 130 are at present occupied. The large rectangular and circular wards, each of which contains 20 beds, the operation theatre, out-patient, general and special, and the pathological departments, have all been erected since 1887. They are specially designed with a view of offering the greatest facilities for clinical work, and contain all the most recent and approved hygienic and antiseptic requirements for the proper care of the sick and for the treatment of disease. Medical practitioners are cordially invited to see the general and special practice of the hospital. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. Further particulars from Peyton T. B. Beale, F.R.C.S., Hon. Secretary Medical Committee, 61, Grosvenor-street, W.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Physicians for In-patients: Miss Cock, M.D., and Miss Walker, M.D. Surgeons for In-patients: Mrs. Scharlieb, M.D., M.S., and Mrs. Boyd, M.D. Physicians and Surgeons for Out-patients: Miss Webb, M.B., Miss Macdonald, M.B., and Miss Aldrich Blake, M.D., M.S. Ophthalmic Surgeon: Miss Ellaby, M.D. Assistant Physicians for Out-patients: Miss Chadburn, M.B., Mrs. Wilks, M.D., and Miss Caine, M.D. Physician for Maternity Department: Miss Harris, M.B. Anæsthetist: Mrs. Keith, L.R.C.P. A considerable number of the students hold posts in the New Hospital under the visiting staff, and in return for much valued clinical teaching they do the work assigned to students in the wards of a general hospital. Secretary: Miss M. M. Bagster.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873.)—Physicians: Dr. Wilde, Dr. J. J. Ridge, and Dr. Fenwick. Surgeon: Dr. W. J. Collins, F.R.C.S. Dental Surgeon: Mr. A. Alexander. The hospital contains 110 beds. The in-patients in 1897 were 1175, and the out-patients and casualties numbered 18,387 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Special departments for Ophthalmology and Gynæcology. Operations: Mondays and Thursdays, 3.30 P.M. Classes will be held during the winter and summer sessions for students preparing for the final examinations at the Colleges and the Universities. Appointments, vacancies for which are advertised in the medical journals: Registrar and Pathologist; Resident Medical Officer and Assistant Resident Medical Officer. For particulars as to hospital practice and classes apply at the hospital to Dr. W. J. Collins.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—The hospital, with the Finchley branch, contains 200 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday at 2 P.M. In- and out-patient practice and electrical-room treatment at that hour. Physicians: Drs. Hughlings Jackson, Buzzard, Bastian, and Gowers. Physicians for Out-patients: Drs. D. Ferrier, Ormerod, Beevor, and Tooth. Assistant Physicians: Drs. James Taylor and W. S. Colman. Surgeons: Messrs. Victor Horsley and C. A. Ballance. Ophthalmic Surgeons: Messrs. R. Brudenell Carter and Marcus Gunn. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Sir Felix Semon. Anæsthetist: Dr. R. T. Bakewell. Pathologist: J. Risien Russell. Registrar: Dr. A. J. Whiting. House Physicians: Drs. Stewart and Collier. The hospital has been recognised by the conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, and hospital practice should be addressed to the Secretary and Director at the hospital.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physician: Dr. George B. Brodie. Consulting Surgeon: Sir William MacCormac. Physicians to In-patients: Dr. W. C. Grigg and Dr. W. S. A. Griffith. Physicians to Out-patients: Dr. W. Rivers Pollock and Dr. W. J. Gow. This hospital, which has been recently enlarged, receives over 1100 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all Universities, Colleges, and licensing bodies. Pupil midwives and monthly

Digitized by Google

nurses are received and specially trained. Fees: Medical Students, £8 8s. for four weeks; Qualified Medical Practitioners £8 8s. for four weeks. Pupil Midwives, £26 5s. for three months (including board and lodging); Pupil Nurses, £15 15s. for twelve weeks (including board and lodging). There is a residence for students and qualified practitioners within fifty yards of the hospital, with which it is in telephonic communication. Terms for residence and partial board one guinea per week. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

SEAMEN'S HOSPITAL SOCIETY, Dreadnought Hospital, Greenwich, S.E. (225 beds). Royal Victoria and Albert Docks Hospital, E. (23 beds). Dispensaries: East India Dock-road, E., and Gravesend.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students, and students are allowed to attend the general practice at either of the hospitals. Facilities are given for the study of Eastern diseases. Dreadnought Hospital:—Consulting Physician: Dr. Robert Barnes. Consulting Surgeon: Mr. J. N. Davies-Colley. Visiting Physicians: Dr. John Curnow and Dr. John Anderson, C.I.E. Visiting Surgeon: Mr. G. Robertson Turner. Ophthalmic Surgeon: Mr. D. S. Gunn. Principal Medical Officer: Mr. W. Johnson Smith. House Physician: Mr. A. Earnshaw. House Surgeon: Mr. Humphrey Allen. Branch Hospital at the Royal Victoria and Albert Docks:—Visiting Physician: Dr. Patrick Manson. Visiting Surgeons: Mr. W. Johnson Smith and Mr. W. Turner. House Surgeons: Mr. F. K. Wilson and Mr. J. W. E. Cole. East and West India Docks Dispensary:—Surgeon: Mr. J. R. Prior. Gravesend Dispensary: Surgeon: Mr. C. E. Robbs. Secretary: Mr. P. Michelli.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C., contains 186 beds, divided into 88 medical, 73 surgical, and 25 for special and infectious cases, besides 52 beds at the convalescent branch, Highgate. The hospital having been recognised by the conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students who have completed four years of medical study and also to qualified medical men. Appointments are made every three months to six medical clerkships and six surgical clerkships, which are open to students of the hospital. Lectures or demonstrations are given once or twice every week during both winter and summer sessions, which qualified practitioners are invited to attend free of charge. The sessions are of ten weeks' duration, and begin in October, January, and March. Fees for hospital practice, three months, 2 guineas; perpetual, 3 guineas. Prospectuses and further information will be forwarded on application to the Secretary, Mr. Adrian Hope, at the hospital.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital, founded in 1804 and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by 1968 persons. In the same year the out-patients were 25,051 and the attendances, 129,950. Operations are performed daily from 10 A.M. to 1 P.M., and three surgeons attend on each day. Students are admitted to the practice of the Hospital. Fee for six months, £3 3s.; perpetual, £5 5s. Courses of instruction on the following subjects are given at the Hospital periodically: (1) the use of the ophthalmoscope; (2) errors of refraction; (3) external diseases of the eye; (4) surgical anatomy of the eye. Systematic instruction is also given in the laboratory of the hospital on the pathology of the eye. Perpetual students are admitted to the lectures free. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 35 beds; and the patients, who number 11,000 annually, are seen at 1 P.M., and operations performed daily at 2 P.M. The following are the days of attendance of the surgeons: Mr. Hartridge and Mr. Dodd, Mondays and Thursdays; Mr. Frost and Mr. D. Gunn, Tuesdays and Fridays; and Mr. Juler and Mr. Griffith, Wednesdays and Saturdays. The practice of the hospital is open to practitioners and students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house surgeon and clinical assistant. Special demonstrations and lectures will be given during the session, commencing in October; for details see weekly journals. Clinical Assistants (who must be duly qualified) to the Surgeons are appointed for periods of six months. Secretary: Mr. T. Beattie-Campbell.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.—The out-patient practice is open to the medical profession at the following times: Every day, from 2 to 4 P.M., and Thursday mornings from 10.30 to noon. Specially selected Clinical Demonstrations, also demonstrations on the different diseases presenting themselves in the out-patient department, followed by Lectures, will also be given.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, Henrietta-street, Covent-garden. Established 1860. New Hospital opened, 1882.—Consulting Surgeon: Mr. F. R. Heycock. Honorary Surgeons: Mr. F. Swinford Edwards, Mr. E. Hurry Fenwick, Mr. Reginald Harrison, and Mr. P. J. Freyer. Pathologist: Mr. E. Hurry Fenwick. The hospital contains 24 beds for men, 2 beds for women, and 1 private ward. Consultations are held and operations are performed each Wednesday and Friday at 2 P.M. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 19; average out-patients seen daily, 100.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE (with which is amalgamated the COLLEGE OF STATE MEDICINE).—The winter session commences on Oct. 4th and the summer session on May 1st. The new building at Chelsea Bridge is now open for instruction and research. Courses in Bacteriology in relation to Medicine and Pathology and to Hygiene are given in the bacteriological laboratories and courses of instruction in Water and Hygiene Analysis for the D.P.H. examinations and research work are conducted in the chemical department. There is also a large biological-chemical laboratory for instruction and research and a photo-micrographical department. Every facility is given for original research work. Director and Hon. Sec.: Allan Macfadyen, M.D., B.Sc., to whom all applications should be made, assisted in the Bacteriological Department by R. T. Hewlett, M.D., M.R.C.P., and A. G. R. Foulerton, F.R.C.S., D.P.H., and in the Chemical Department by A. Harden, Ph.D., B.Sc. Photo-micrographic Department: J. E. Barnard. Assistant Secretary: G. Cooper.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, Dr. J. A. Coutts, and Dr. Dawson Williams. Surgeons: Mr. R. W. Parker and Mr. L. A. Dunn. Assistant Physicians: Dr. T. H. Arnold Chaplin, Dr. J. A. Hayward, Dr. Morley Fletcher, and Dr. E. Graham Little. Assistant Surgeon: Mr. H. B. Robinson. Pathologist and Registrar: Mr. T. D. Lister. Medical Officer for the Casualty Department: Dr. F. W. Robertson. Resident Medical Officer: Dr. Joseph Shardlow. House Surgeon: Mr. W. Evans. House Physician: Dr. Elwin H. T. Nash. Secretary: Mr. Thomas Hayes. The hospital maintains 102 cots, and on an average 178 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Practitioners and students are admitted to the practice of the hospital in both the wards and out-patient departments and clerkships and dresserships can be obtained. A special course of clinical lectures is delivered by members of the staff on Fridays, at 4 P.M., during the Medical Sessions, of which further particulars will be announced. Any additional information may be obtained on applying to Mr. H. Betham Robinson or to Mr. Thomas Hayes, the secretary.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physicians: Dr. W. S. Playfair, Dr. J. F. Goodhart, and Dr. Frederick Taylor. Physicians: Drs. Nestor Tirard and Frederick Willcocks. Physicians to Out-patients: Drs. George Carpenter and W. Soltau Fenwick. Consulting Surgeons: Messrs. H. G. Howse and R. Clement Lucas. Surgeons: Messrs. F. S. Eve and A. H. Tubby. Surgeons to Out-patients: Messrs. F. C. Abbott and Walter Edmonds. Dental Surgeon: Mr. R.

Denison Pedley. Senior Resident Medical Officer: Mr. J. L. Prain. Junior Resident Medical Officer: Mr. O. K. Williamson.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W.—The hospital contains 60 beds (10 beds were taken out as a precaution against infection by increasing superficial area) and has a large out-patient department (over 1000 weekly); the home at Broadstairs has 50 beds. Consulting Surgeon: Mr. Cowell. Physicians: Dr. Montague Murray and Dr. Walter Carr, Drs. Humphry D. Rolleston, Raymond Crawfurd, Arthur C. Latham, and William Cecil Bosanquet. Surgeons: Messrs. Pick and D'Arcy Power. Surgeons to the Out-patients: Messrs. Raymond Johnson and H. F. Waterhouse. Ophthalmic Surgeon: Mr. W. J. Holmes Spicer. Dental Surgeon: Mr. C. E. Wallis. Anæsthetists: Dr. Paul Frank Moline and Dr. C. J. Harrison. House Surgeon: Mr. J. A. Belcher. House Physician: Mr. Sydney Turner. House Surgeon to Out-patients: Mr. J. Stansfield. Consulting Physicians: Sir Wm. Broadbent, Bart., and Dr. Ridge Jones. Secretary: Mr. A. Cameron Skinner. Out-patients are seen as under:—Medical and Surgical Cases: Mondays and Thursdays, 9.30 A.M. and 1.30 P.M.; Thursdays and Fridays, 1.30 P.M.; Wednesdays, 9.30 A.M. Dental Cases: Saturdays, at 9 A.M.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 160 beds, of which 101 are at present in use. The remaining 60 beds will be opened in November. About 1700 in-patients and 32,000 out-patients, whose attendances number 75,000, are treated annually. Physicians: Drs. D. W. C. Hood, F. G. D. Drewitt, and J. B. Ball. Physician for Diseases of Women: Dr. J. A. Mansell Moullin. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and S. Paget. Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Assistant Physicians: Drs. Seymour Taylor, W. A. Turner, A. Whitfield, and A. P. Beddard. Assistant Physician for Diseases of Women: Dr. G. H. Drummond Robinson. Assistant Surgeons: Messrs. L. A. Bidwell, G. L. Cheatle, and W. McAdam Eccles. Surgeon-Dentist: Mr. H. Lloyd Williams. Physician-in-Charge of Throat and Nose and Aural Department: Dr. J. B. Ball. Surgeon-in-Charge of Orthopædic Department: Mr. C. B. Keetley. Pathologist: Dr. A. P. Beddard. Dermatologist: Dr. P. S. Abraham. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Assistant Administrator of Anæsthetics: Messrs. E. W. Lewis and G. P. Shuter. Electrician: Dr. W. A. Turner. Secretary: Mr. R. J. Gilbert. Attached to the hospital is the West London Post-graduate College. The practice of the Hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms daily, and demonstrations are given in the wards on certain fixed days. Post-graduate lectures and demonstrations are given on Wednesdays and Fridays; notice of the commencement of each course is advertised in the medical journals. The accommodation for post-graduates consists of a large lecture room together with reading and writing rooms, &c. The hospital has a fully-equipped pathological laboratory at which instruction can be given in elementary bacteriology. The fees for hospital practice, including lectures, are £3 3*s.* for 3 months or £5 5*s.* for one year. Further information can be obtained on application to the Dean, Mr. L. A. Bidwell, at the hospital.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E. For the sick children of the poor under twelve years of age. Established 1867. City Offices: 27, Clement's-lane, E.C.—Fifty-seven beds. Last year 772 in-patients and 14,947 out-patients (representing 54,352 attendances) were relieved, 210 of the in-patients being under two years of age. Consulting Physicians: Drs. A. E. Sansom, W. Cayley, F. C. Turner and W. Pasteur. Consulting Surgeons: Messrs. Jonathan Hutchinson, Waren Tay, R. J. Godlee and Bilton Pollard. Physicians: Drs. W. A. Wills, James Taylor, J. H. Sequeira, and J. Porter Parkinson. Surgeons: Messrs. H. Percy Dean and A. B. Roxburgh. Resident Medical Officer: C. G. Burton; also a House Physician and House Surgeon. Ophthalmic Surgeon: Mr. Sydney Stephenson (Wednesday, 9.30 A.M.). Dental Surgeon: Mr. John W. Pare (Tuesday and Friday, 9.30 A.M.). Matron: Miss E. W. Curno. Secretary: T. Glenton-Kerr. The surgeons attend on Wednesdays at 2 P.M. and Fridays at 9 A.M.; the physicians daily at 2 P.M. Applications for permission to attend the practice of the hospital should be addressed to the secretary.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Consulting Physician: Dr. Donald W. C. Hood. Physician: Dr. Harry Campbell. Surgeon: Mr. Frederic Durham. Assistant Physicians: Drs. W. Knowsley Sibley, Leonard G. Guthrie, and G. A. Sutherland. Assistant Surgeons: Messrs. M. P. Mayo Collier, J. Jackson Clarke, and George Templeton. Physician for Diseases of the Skin: Dr. J. Herbert Stowers. Obstetric Physician: Dr. John Shaw. Ophthalmic Surgeon: Dr. W. J. Collins. Dental Surgeon: Mr. C. F. Rilot. The hospital, which was established in 1878, provides 53 beds. The average number occupied last year was 47. It is a general hospital. There are two spacious wards for men and women respectively. The children's wards contain 18 cots. There are two Resident Medical Officers—an honorarium at the rate of £50 per annum attaches to the senior post. Operation day, Thursday at 2.30 o'clock. Further particulars from J. Herbert Stowers, M.D., Hon. Sec., Medical Committee, 128, Harley-street.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were upwards of 46,000 attendances in the Out-patient Department last year, and the new patients number over 16,000 yearly. Operations are performed and out-patients are seen daily at 2 P.M. The following are the days of attendance:—Mr. M. M. McHardy, Tuesdays; Mr. J. G. Mackinlay, Thursdays; Dr. W. J. Collins, Wednesdays and Fridays; and Mr. L. V. Cargill, Mondays and Saturdays. Qualified practitioners and students are admitted to the practice of the hospital upon the recommendation of the medical staff. Tuition is given daily in the out-patient department, beginning at 2 P.M. The students need not necessarily possess a registerable qualification. They work under the guidance of the surgeons and clinical assistants, and may become eligible for clinical assistantship, house surgeonship, and registrarship, as vacancies arise. Fees: £2 2*s.* for 3 months, £3 3*s.* for 6 months, and £5 5*s.* perpetual. Qualified students of the hospital are eligible for the offices of registrar and house surgeon, and may be appointed clinical assistants upon the recommendation of the medical staff for a term of 6 months, and are eligible for re-election. Courses are held on Ophthalmoscopy, Refraction and Diseases of the Eye, fee, £1 1*s.* for each course, but perpetual students may attend each course once without extra fee. Pathology Class, £1 1*s.* extra to cover cost of materials. Tutorial or coaching classes for the various examinations arranged as far as possible to suit candidates. The classes will begin in October, if there are sufficient applications.

VOLUNTEER MEDICAL STAFF CORPS (LONDON COMPANIES), Calthorpe-street, Gray's-inn-road, W.C. — Hon. Commandant: Surgeon-General Sir William Guyer Hunter, K.C.M.G., Q.H.S., V.D. Commandant: Surgeon-Lieutenant-Colonel J. S. Squire, V.D. The Volunteer Medical Staff Corps bears the same relation to the Volunteer Army as the Medical Staff Corps bears to the regular Army. The course of training has the great advantage of affording, in addition to a knowledge of ordinary military duties, special ambulance instruction useful in all ranks of life. All who have gone through the ranks of this corps are capable of rendering valuable aid in any accident, and in cases of emergency may be the means of saving lives which would otherwise be lost. In addition to the Company and Battalion drills of an ordinary infantry corps, the special training includes stretcher and waggon and cacolet drill; the use of improvised seats and stretchers; the use and application of bandages, splints, &c.; lectures by the officers on first aid to the injured, and on the elements of anatomy, physiology, hygiene, and nursing, which are so arranged as not to interfere with the lectures, &c. carried on at the various hospitals in London. There is also a Shooting Club in the corps, in which instruction in, and facilities for, the practice of rifle shooting are given. There is a Transport Section in connexion with the corps, the members of which go through a course of instruction in riding and driving and transport work with the regular troops. There are also sections of Cyclists and Signallers. A Gymnastic Class meets once a week at headquarters, under an instructor who teaches boxing and fencing. Lectures are delivered during the winter session. The new headquarters contain a fine drill hall, mess-rooms, canteen, &c., where dinners, suppers, dances, and smoking concerts can be held at any time. The Adjutant, Captain G. T. Rawnsley, will give any information respecting the above on application to the headquarters, Calthorpe-street, Gray's-inn-road, W.C.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: J. Norman Collie, Ph.D., F.R.S. (Dean of the school). Botany: Professor Reynolds, Green, M.A., Sc.D., F.R.S., F.L.S. Materia Medica and Pharmacy: Professor Greenish, F.I.C., F.L.S. The session commences on Monday, Oct. 4th. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges. Application for admission to the school, or for further information, may be made to the Dean of the school, 17, Bloomsbury-square, London, W.C.

WESTMINSTER COLLEGE OF CHEMISTRY AND PHARMACY, Trinity-square, Borough, S.E.—Principals, G. S. V. Wills, F.L.S., and H. Wootton, B.Sc. Lond. In addition to the ordinary courses for Pharmaceutical and other students for many years past ladies have been prepared for the Dispenser's Examination of the Apothecaries' Hall. Last session a number of them passed the examination. For further particulars, prospectus, &c., application should be made to E. Walden, Secretary.

ROYAL COLLEGE OF SCIENCE, London (with which is incorporated the ROYAL SCHOOL OF MINES).—Mechanics and Mathematics: Professor J. Perry, F.R.S. Biology: Professor G. B. Howes, F.R.S. (Zoology), and Professor J. B. Farmer, M.A. (Botany). Chemistry: Professor W. A. Tilden, F.R.S., and Dr. W. P. Wynne, F.R.S. Physics: Professor A. W. Rücker, Sec. R.S., and Mr. W. Watson, B.Sc. Astronomical Physics: Professor Sir J. N. Lockyer, K.C.B., F.R.S. Geology: Professor J. W. Judd, C.B., F.R.S. Metallurgy: Professor W. C. Roberts-Austen, C.B., F.R.S. Mining: Professor C. Le Neve Foster, F.R.S. The College re-opens on Wednesday, Oct. 6th, 1897. Communications should be addressed to the Registrar, Royal College of Science, South Kensington, S.W.

ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, Faraday House, 8 and 10, Charing-cross-road, W.C.—Principal, Mr. Hugh Erat Harrison, B.Sc. Lond., F.C.S., A.M.I.C.E., M.I.E.E. Instructor in Mathematics: Alexander Russell, M.A. Glasgow and Cambridge. Instructor in Chemistry: Chas. J. Wilson, F.I.C., F.C.S. This institution, in addition to its ordinary course of training in electrical engineering, which occupies two or three years, also arranges for special instruction in all branches of electricity and in Roentgen Ray photography, either by private tuition or by a specially arranged course at the college or at the works of the companies with which it is associated. There are Entrance Scholarships of the value of 80 and 50 guineas, and Exhibitions of 40 guineas. Particulars may be obtained on application to the Secretary, Mr. Howard Foulds, Faraday House, Charing-cross-road, W.C.

PROVINCIAL MEDICAL SCHOOLS AND HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.[1]

MASON UNIVERSITY COLLEGE, BIRMINGHAM.—Two Ingleby Scholarships are offered annually after examination in Obstetric Medicine and Surgery and Diseases of Women and Children. The Scholarships are open to students who have completed two years of their curriculum in this college. One or more Sydenham Scholarships are offered annually of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. The Scholarships are held for three years, subject to good behaviour. A Queen's Scholarship is offered annually of the value of 30 guineas. It may be held for three years, one-third being paid each year, subject to good behaviour. A Sands Cox Scholarship is offered annually, of the same value as the last, and is held under similar conditions. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. There are Faculties of Arts, Science, and Medicine, and students are prepared for the various examinations of the University of London. The medical courses qualify for the diplomas of all Licensing Bodies and for the degrees in Medicine and Surgery of British Universities. There are various Scholarships, Entrance and otherwise. The Dental Department, in conjunction with the General, Queen's, and Dental Hospitals, affords a complete curriculum for all Dental diplomas. The Library contains upwards of 25,000 volumes. Syllabuses containing full information as to the various courses of instruction, lecture days and hours, fees, scholarships, &c., will be forwarded on application to the Registrar.

[1] For Scholarships see page 644 *et seq.*

THE QUEEN'S HOSPITAL, BIRMINGHAM. — Consulting Physicians: Sir James Sawyer, Knt., M.D., F.R.C.P., F.R.S.E., J.P., and Cornelius W. Suckling, M.D., M.R.C.P. Consulting Surgeons: Furneaux Jordan, F.R.C.S., and J. St. S. Wilders, M.R.C.S. Physicians: Alfred H. Carter, M.D., F.R.C.P., Arthur Foxwell, M.A., M.D., F.R.C.P., and O. J. Kauffmann, M.D., M.R.C.P. Surgeons: Bennett May, B.S., F.R.C.S., Jordan Lloyd, M.S., F.R.C.S., and Frank Marsh, F.R.C.S. Ophthalmic Surgeon: Priestley Smith, M.R.C.S. Obstetric Officer: C. E. Purslow, M.D., M.R.C.P. Physician for Out-Patients and Pathologists: J. Douglas Stanley, M.D., M.R.C.P. Casualty Surgeons: J. T. J. Morrison, M.A., B.C., F.R.C.S., J. Hazlewood Clayton, M.B., M.R.C.S., and C. A. Leedham-Green, F.R.C.S. Provision has recently been made for an increase in the number of beds to 132 for the reception of accidents and urgent medical, surgical, ophthalmic, and obstetric cases. The in-patients treated last year amounted to 1,913, the out-patients to 28,549.

GENERAL HOSPITAL, BIRMINGHAM.—Consulting Physicians: Sir Walter Foster and Sir Willoughby Wade. Physicians: Drs. Rickards, Saundby, Simon, and Wilson. Surgeons: Messrs. Chavasse, Barling, Haslam, and Heaton. Obstetric Officer: Dr. Malins. Assistant Physicians: Drs. Short and Russell. Assistant Surgeons: Messrs. Lucas and Gamgee. Assistant Obstetric Officer: Dr. Thos. Wilson. Beds, 308; average occupied, 270. Patients in 1897: in-patients, 4173; out-patients, 54,217.

UNIVERSITY COLLEGE, BRISTOL (Faculty of Medicine).—Students can complete in Bristol the entire course of study required for the Medical and Surgical degrees of the University of London, and for the diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given in the Faculty of Arts and Science are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; whilst the Faculty of Medicine, the Royal Infirmary, and the General Hospita together provide for every detail of the professional curriculum required by the University of London and the above examining boards. All necessary information may be obtained from the Dean of the Faculty of Medicine, Professor E. Markham Skerritt, M.D., F.R.C.P.

UNIVERSITY COLLEGE, CARDIFF, MEDICAL SCHOOL.—The winter session will commence on Monday, Oct. 3rd. The annual address will be given by Dr. Robert Saundby in the chemical theatre on the evening of Oct. 7th, on Modern Universities. All classes are open to both men and women students who may spend three out of their five years of medical study at Cardiff. The courses of study are recognised as qualifying for the Preliminary Scientific and Intermediate Examination in Medicine in the University of London and for the corresponding examinations in the Universities of Edinburgh, Glasgow, Aberdeen, Durham, and the Royal University of Ireland. Students who are preparing for these examinations may compound for their courses by paying a fee of £57 10*s.*, while a composition fee of £35 includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board or of the Society of Apothecaries, London. In all cases the composition fees may be paid by instalments. The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions, varying in value from £10 to £30 per annum, offered for competition at University College, Cardiff, in September next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registar. Physics.—Professor J. Viriamu Jones, M.A. Oxon., B.Sc. Lond., Fellow of University College,

London, F.R.S. Assistant Professor: A. L. Selby, M.A., Fellow of Merton College, Oxford. Demonstrator and Assistant Lecturer: W. S. Hensley, B.A., Christ's College, Cambridge. Chemistry. — Professor C. M. Thompson, M.A., Trinity College, Cambridge, D.Sc. Lond., F.C.S. Demonstrators and Assistant Lecturers: E. P. Perman, D.Sc. Lond., and A. A. Read, F.I.C., F.C.S. Biology.—Professor W. N. Parker, Ph.D. Freiburg, F.Z.S. Lecturer in Botany.—A. H. Trow, B.Sc. Demonstrator and Assistant Lecturer in Biology.—H. S. Harrison, A.R.C.S. Anatomy.—Professor Francis Dixon, B.A., M.B. Physiology.—Professor John Berry Haycraft, M.D., D.Sc., F.R.S.E. Demonstrator and Assistant Lecturer.—S. C. Mahalanopis, B.Sc., F.R.S.E. Materia Medica: D. R. Paterson, M.D. Further information may be obtained from Professor A. Francis Dixon, Dean of the Medical Faculty. Hospital instruction is given at Cardiff Infirmary, which is within five minutes' walk of the College. This institution contains 200 beds and has a large out-patient department as well as special departments for the Eye, Ear, and Throat.

BRISTOL ROYAL INFIRMARY (Founded 1735).—270 beds. Honorary and Consulting Physicians: Dr. Edward Long Fox and Dr. William H. Spencer. Honorary and Consulting Surgeon: Mr. Edmund C. Board. Physicians: Dr. R. Shingleton Smith, Dr. Henry Waldo, Dr. John E. Shaw, and Dr. Arthur B. Prowse. Obstetric Physician: Dr. W. C. Swayne. Assistant Physicians: Dr. P. Watson Williams and Dr. F. H. Edgeworth. Surgeons: Mr. Arthur W. Prichard, Mr. W. H. Harsant, Mr. J. Paul Bush, and Mr. G. Munro Smith. Ophthalmic Surgeon: Mr. F. Richardson Cross. Assistant Surgeons: Dr. James Swain and Mr. Thomas Carwardine. Dental Surgeon: Mr. W. R. Ackland. Pathologist: Dr. Theodore Fisher. Bacteriologist: Dr. J. Odery Symes. House Surgeon: Mr. H. F. Mole. House Physician: Dr. E. H. E. Stack. Resident Obstetric Officer: Mr. A. L. Fleming. Anæsthetist and Junior House Surgeon: Mr. R. H. Chilton. Casualty Officer: Mr. S. V. Stock. Secretary and House Governor: Mr. E. A. Leonard.

Scholarships and Prizes.—Two Entrance Scholarships, 35 guineas and 10 guineas: examination third Saturday in October in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clark Prize, 11 guineas; Crosby Leonard Prize, 7 guineas; Tibbitts Prize, 9 guineas; Augustin Prichard Prize, 7 guineas; Midwifery Prize, 3 guineas in books or instruments; Four Pathological Prizes, 3 guineas each; Ophthalmic Prize, 3 guineas in books or instruments; Dental Prize, 3 guineas in books or instruments.

There are five resident appointments—viz., House Surgeon, House Physician, Resident Obstetric Officer, Anæsthetist and Junior House Surgeon, and Casualty Officer, the last two of which are intended specially for qualified students of the Bristol Royal Infirmary, who are elected after a practical examination. Medical Registrars and Surgical Registrars are appointed for periods of six months. The Dressers reside in the Infirmary in rotation, free of expense. The Maternity student also has rooms in the Infirmary. The whole of the clinical work is carefully arranged to meet the requirements of the five years' curriculum. There is class instruction in the wards by the physicians and surgeons on five days a week, in addition to the regular clinical lectures. There are special departments for Diseases of Women, the Eye, Ear, Throat, &c, with Clerkships and Dresserships attached, and there is a large Ward for Children only. Practical instruction in Dental Surgery on Tuesdays and Fridays. Clinical Clerkships and Dresserships, 5 guineas for each six months. Perpetual Medical and Surgical Practice, 35 guineas in one sum.

Further information can be obtained from Dr. Arthur B. Prowse, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—200 beds. Physicians: Drs. Markham Skerritt, Harrison, and Michell Clarke. Physician Accoucheur: Dr. W. H. C. Newnham. Physician to Throat and Nose: Dr. Barclay Baron. Assistant Physician: Dr. Parker. Assistant Physician Accoucheur: Mr. D. C. Rayner. Surgeons: Messrs. Pickering, Barclay, Morton, and Lansdown. Ophthalmic Surgeon: Mr. Walker. Assistant Surgeon: Dr. Firth. Anæsthetist: Mr. Freeman. House Surgeon: Dr. Randall. Assistant House Surgeon: E. G. Bunbury. Casualty Medical Officer: R. F. P. Mackie. Clinical Clerkship, six months, £5 5*s*. Dresserships, six months, £5 5*s*. Obstetric Clerkship, three months, £3 3*s*. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women and in Dental Surgery. Further information may be obtained of the Secretary, at the hospital, or from Dr. Michell Clarke, Dean of the Hospital Faculty.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment. The composition fee for pupilship is 8 guineas.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:— Four University of Durham Scholarships, value £25, tenable for four years, for proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value interest of £400, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest of £500, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680 for Comparative Pathology. The Stephen Scott Scholarship in Surgery, value the interest of £1000. Heath Scholarship: The late George Yeoman Heath, M.D., D.C.L., F.R.C.S., President of the University of Durham College of Medicine, bequeathed the sum of £4000 to found a Scholarship in Surgery, the interest to be awarded every second year; the next award will be in 1900. The Gibson Prize, interest on £225, in the department of Midwifery and Diseases of Women and Children. At the end of each session Prizes of Books and Honours Certificates are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, Prosectors, and Assistant Demonstrators of Physiology and Pathology are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Throat and Ear Department, and Skin Department, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Physicians: Drs. Drummond, Oliver, Limont, and Murray. Surgeons: Drs. Hume, Page, Mr. Williamson, and Mr. Rutherford Morison. Assistant Surgeons: Mr. Walter Ridley, Mr. A. M. Martin, Mr. H. B. Angus, and Mr. J. V. W. Rutherford. Pathologist: Dr. Beattie. Dental Surgeon: Mr. R. L. Markham. Skin Department: Dr. Limont. Eye Department: Mr. Williamson. Throat and Ear Department: Mr. Ridley. Anæsthetist: Dr. W. D. Arnison. Surgical Registrars: Mr. J. D. Wardale and Mr. John Clay. The infirmary contains 280 beds. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given by the Pathologist as opportunity offers. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Northumberland County Asylum, Morpeth. A Special Course of Instruction is given in the City Hospital for Infectious Diseases by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 447 in-patients, medical and surgical, including forty-two beds at a "semi-convalescent home" in the country. During the last year 6116 in-patients and 37,623 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and

Digitized by Google

Skin Clinics, are in operation. The Public Dispensary, the Hospital for Women and Children, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students. Four years ago the new buildings of the Medical School were opened by their Royal Highnesses the Duke and Duchess of York. Erected on a commanding site, close to the Infirmary, the new School of Medicine contains complete accommodation for the training of medical students upon the most approved modern methods. A very fine dissecting-room, extensive laboratories for Physiology and Pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large Library, and separate Museums for Pathology and Anatomy—these are some of the most striking features of the new buildings. Careful provision for the convenience of students, in the shape of a common-room, a refectory, &c., has also been made a feature of the school. The classes in Systematic and Practical Chemistry, Physics and Biology, are held in the Science and Arts Department of the College, in College-road. Two Entrance Scholarships are offered: one, of the value of 64 guineas, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students (for some of them, however, a registered legal qualification is required); senior and 3 junior anæsthetists, pathological curator, resident medical officer, resident surgical officer, resident casualty officer, resident ophthalmic officer, appointed for twelve months, and eligible for re-election; resident obstetric officer and 4 house surgeons, for twelve months; 3 house physicians, for six months; 30 physicians' clerks, for six months; 32 surgeons' dressers, for six months; 16 ophthalmic and aural surgeons' dressers, for three months; 12 gynæcological ward clerks, for three months; 16 gynæcological out-patient clerks, for three months; 24 assistant physicians' clerks, for three months; 24 assistant surgeons' dressers, for three months; 8 out-patient ophthalmic and aural dressers; 32 dressers in the casualty-room, for three months; 32 post-mortem clerks, for three months.

There are appointments open to students in other medical institutions in the town and also in the West Riding Lunatic Asylum.

UNIVERSITY COLLEGE, LIVERPOOL: MEDICAL FACULTY.—The new Physiological and Pathological Laboratories are now in course of erection, and will be ready for occupation during the Winter Session (1898-99). The Chemical Laboratories have been extended at a cost of about £10,000, so as to provide *inter alia* more complete accommodation for medical students and those engaged in Laboratory work for Diplomas in Public Health. Steps are being taken for the extension of the Anatomical Department, and the first instalment of new Anatomical and Surgical Laboratories has been already erected at a cost of £2000 in the form of permanent Anatomical out-buildings and courtyard. The buildings include mortuary, store-rooms, museum work-rooms, and macerating room, along with lavatories, &c. The erection of new Anatomical and Surgical Laboratories will be commenced as soon as practicable. The dissecting-room and theatre have been provided with the electric light. The chair of Pathology has adequate temporary accommodation in Ashton Hall, an institute adjacent to the College, which contains ample class-room and laboratory accommodation for study and research in Pathology and Bacteriology. The museums of Anatomy, Pathology, Materia Medica, and Public Health are furnished with complete provision for the needs of students and have recently been reorganised and revised.

Fees.—The composition fee for lectures and classes is £24 15*s.* for Preliminary Science Classes; £60 for the Medical Classes required for the Victoria University degrees; £70 for all the classes required for the diplomas of the Conjoint Boards. The medical composition fees are payable in two instalments at intervals of twelve months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

Appointments.—Three house surgeons, three house physicians, and one external house surgeon to the Thornton Wards are appointed for six months after (if necessary) competitive examination. Candidates must have a legal qualification. Three clinical clerks for each physician, three or more dressers for each surgeon, and two clerks to the Thornton Wards for Diseases of Women are appointed every three months. Post-mortem clerks are appointed for six weeks; all students are required to perform this duty before the schedule for the Final Examination is signed. Clinical assistants are appointed from among the senior students.

There is a School of Dental Surgery in connexion with the medical faculty. The curriculum includes Lectures and Demonstrations on all the subjects required for the Licences in Dental Surgery of the Royal Colleges of Surgeons of London, Edinburgh, and Dublin, and of the Faculty of Physicians and Surgeons of Glasgow. In addition, Laboratory Courses are conducted in Dental Histology and Dental Pathology.

Practical instruction in Dentistry is given at the Dental Hospital in Mount Pleasant.

Fees.—A payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months), entitles the student to attendance on all lectures and demonstrations (medical and special) required for the Dental Licence of the Royal College of Surgeons. The fee for two winters' surgical practice is £10 10*s.*, and for two years' dental hospital practice, £12 12*s.* The total expenditure for the whole curriculum is £73 2*s.*

Further information can be obtained from the Dean of the Medical Faculty, Professor Paterson, University College, Liverpool.

SCHOOL OF PHARMACY.—A department of Pharmacy has recently been instituted, comprising the necessary courses for the minor and major examinations of the Pharmaceutical Society in Chemistry, Physics, Botany, Materia Medica and Pharmacy. The composition fee is £17, and the classes may be attended in one or two years.

Prospectus and further information may be had on application to the Registrar, University College, Liverpool.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large building, which forms a part of Owens College. It is provided with large dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, an extension of the school buildings has recently been made. The greater part of the new buildings is devoted to the departments of physiology, pathology, toxicology, anatomy, and public health. The physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. In the toxicological department there is a large laboratory, capable of accommodating fifty students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology; also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry. In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology. A large room is provided in the new buildings for a museum of apparatus, models, plans, and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics, and sanitary engineering. In addition, a large lecture theatre for general purposes, accommodating 250 students, has been provided, and the existing accommodation for students is supplemented by the provision of a larger common room. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, as well as in a fever hospital, a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following entrance

Digitized by Google

scholarships are offered for award to persons proposing to enter a medical course of study at the College:—Seaton.—One of £40, tenable for two years. Subjects: Greek and Latin Translation at sight, and Prose Composition. Credit given for knowledge of Mathematics (Geometry and Algebra); Elements of English Language, Literature, and History; French and German. Rogers.—One of £40, tenable for two years. Subjects as in Seaton. Dalton.—Two of £40, tenable for two years. Subjects: Geometry (Euclid I.—IV., and VI., or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive). Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics, Elements of English Language, Literature, and History; French and German. Cartwright.—£35 per annum, tenable for three years. Subjects as in Dalton. Hulme.—£35, tenable for three years. Subjects: English Language (Grammatical Structure and Outlines of its History); English Literature (an essay on some subject of English literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight, Grammar, and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). James Gaskill.—£40, tenable for two years. Subjects: Mathematics, Geometry (the substance of Euclid I.—IV. and VI.), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry. Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German. Manchester Grammar School.—£18 per annum, tenable for three years. The examinations for all these scholarships are held in the month of May. Kay-Shuttleworth (Sir James Phillips). — £30 per annum, tenable for three years. Subjects: Mathematics, Elementary Mechanics, Chemistry. Dauntesey Medical Scholarships.—Two Scholarships of £35 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the Owens College or any other Medical School in the United Kingdom. Candidates will be examined in Zoology, Botany, and Chemistry. Medals are awarded on the results of the various class examinations at the end of each session. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the Physiological Laboratory of Owens College, has prosecuted the best original investigation in Physiology and has passed a satisfactory examination in Physiology. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology. A Dumville Surgical Prize of £15 is offered annually for proficiency in Clinical Surgery. The Turner Medical Scholarship of £20 is awarded annually. The John Henry Agnew Scholarship in Diseases of Children (£30) is also offered for competition each year. Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY (292 beds). — Consulting Physicians: Drs. Frank Renaud, H. Browne, Sir Wm. Roberts, and Henry Simpson. Consulting Surgeons: Messrs. George Bowring and F. A. Heath. Physicians: Drs. D. J. Leech, J. Dreschfeld, Graham Steell, and Thos. Harris. Assistant Physicians: Drs. J. S. Bury and A. T. Wilkinson. Consulting Obstetric Physician: Dr. Lloyd Roberts. Obstetric Physician: Dr. Archibald Donald. Surgeons: Messrs. Walter Whitehead, Thomas Jones, Jas. Hardie, and F. A. Southam. Assistant Surgeons: Messrs. G. A. Wright and Wm. Thorburn. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Pathological Registrar: Dr. T. N. Kelynack. Medical Registrar: Dr. R. T. Williamson. Surgical Registrar: Mr. H. W. Pomfret. Administrators of Anæsthetics: Mr. Alexander Wilson and Mr. J. W. Smith. Assistant Medical Officers for Home Patients: Mr. W. B. Pritchard and Mr. G. E. Fryer. General Superintendent and Secretary: Mr. W. L. Saunder.

BARNES CONVALESCENT HOSPITAL, Cheadle, Cheshire (in connexion with the Manchester Royal Infirmary; 136 beds).—Secretary: Mr. W. L. Saunder. Resident Medical Officer: Mr. A. R. Stilwell Freeland.

RADCLIFFE INFIRMARY, Oxford (120 beds).—At this infirmary instruction is given to medical students. Clinical lectures are given by the Lichfield Clinical Lecturers in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis, and Surgical Manipulation. Demonstrations of Elementary Pathology are given in the post-mortem room and at the Pathological department of the museum by the Regius Professor of Medicine or his Deputy. Practical Pharmacy is taught in the Infirmary Dispensary. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination or the First Oxford M.B.

UNIVERSITY COLLEGE, SHEFFIELD—DEPARTMENT OF MEDICINE.—The Medical School has been incorporated by Royal Charter with Firth College and the Sheffield Technical School, under the title of University College, Sheffield. An entrance scholarship of the value of £110 is awarded annually to the best candidate (if of sufficient merit) in Mathematics, Elementary Physics, Inorganic Chemistry, Latin, and English. Prizes for Clinical Medicine and Surgery of 10 guineas are offered by the Clinical Committee. Prizes in books and certificates are awarded annually. The medical school is provided with dissecting-room, physiological laboratory, museum, library, and class-rooms. The physiological department has been entirely reconstructed and equipped in memory of the late President of the school, Mr. Wm. F. Favell, and will in future be called the Favell Laboratory. The department consists of a lecture and demonstration theatre, preparing-room, and galvanometer room. In addition to the usual fittings the theatre is provided with a projection lantern microscope for the demonstration of microscopic slides. Each student has his own laboratory bench, with gas, water, electric light, and the requisite apparatus. The department is lighted throughout by electricity. The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. The Sheffield Royal Infirmary contains 240 beds, including Ophthalmic and Dermatological departments, a museum of Pathology, library, and post-mortem theatre, with microscopes and all the appliances for clinical research. New Ophthalmic wards have recently been erected. The Sheffield Royal Hospital contains 125 beds and Dental and Ophthalmic departments, and is recognised by the examining bodies. Perpetual fee for hospital practice £45 in one payment; or by two instalments: £26 on entering for hospital practice, and 22 guineas within twelve months afterwards. Composition fee for lectures and practical courses 60 guineas; or in two instalments: 35 guineas at commencement of medical study, 30 guineas at beginning of the second year. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the Borough Fever Hospitals, and the South Yorkshire Asylum. Mr. C. F. Myers Ward has been appointed Professor of Physiology in place of Dr. Arthur Hall, Mr. R. Favell Professor of Midwifery and Diseases of Women in place of Dr. Keeling, Dr. Arthur Hall Demonstrator of Practical Pathology in place of Dr. Somerville; Dr. Sinclair White has been appointed Honorary Surgeon to the Royal Infirmary in place of the late Mr. G. H. Shaw; Dr. Riseley has been appointed Ophthalmic Surgeon to the Royal Hospital.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and, in case of need, are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the hospital and be supplied with cases of midwifery. Communications should be addressed to the Secretary, York Chambers, York-street, Sheffield.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. H. Davy and William Gordon. Consulting Surgeons: Messrs. A. J. Cumming, T. W. Caird, and James Bankart. Surgeons: Messrs. J. D. Harris, E. J. Domville, Charles E. Bell, and A. C. Roper. House Surgeon: Mr. P. H. Stirk. Assistant House Surgeon: Mr. W. Ashford. The hospital contains 218 beds (including special children's wards), and has a good library, museum, dissecting room and post-mortem room. Attendance on the practice of this

Digitized by Google

hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. There is also a Nurses' Home attached to the Hospital. For further particulars as to fees, &c. apply to the Matron. A new wing has lately been added.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Physician: Dr. William Gordon. Surgical Staff: Messrs. Bankart and Tosswill. Assistant Surgeon and Registrar: Mr. Roper. Secretary: Ernest W. Toby. The infirmary contains fifty beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1897, 2432. Total number of patients since the opening of the Infirmary in 1808, 92,791. Days of admission: Mondays, Tuesdays, and Fridays, at 11 A.M.

KENT AND CANTERBURY GENERAL HOSPITAL.—Opened for the reception of patients April 26th, 1793. 57,245 in-patients and 101,510 out-patients have been admitted since the hospital was opened. The hospital contains 106 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society for £7 7*s*. Operation day, Thursday, 11 A.M. Physician: Dr. Henry Alex. Gogarty. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Frank Wacher, T. Whitehead Reid, J. Greasley, and Sydney Wacher. Dentist: Mr. R. S. N. Faro. House Surgeon: Mr. E. C. Frend. Assistant House Surgeon: Mr. H. C. Manning. Secretary: Mr. Arthur J. Lancaster. Over 700 in-patients, 2000 out-patients and casualties, and 357 dental cases are attended in a year.

LIVERPOOL NORTHERN HOSPITAL (160 beds).[2]—There is a special ward for the treatment of children. Clinical instruction is regularly given by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee. Consulting Surgeons: Mr. W. H. Manifold and Dr. W. Macfie Campbell. Physicians: Dr. E. H. Dickinson, M.A.; Dr. Bushby. Surgeons: Messrs. Chauncy Puzey, Damer Harrisson, and A. H. Wilson. Fees for hospital attendance: Perpetual, £26 5*s*.; one year, £10 10*s*.; six months, £7 7*s*.; three months, £4 4*s*.; Practical Pharmacy, £2 2*s*. Students can enter to the medical or the surgical practice separately on payment of half the above fees. The foundation-stone of a new hospital of not less than 200 beds has been laid during the past year, in which there will be every facility for clinical teaching and accommodation for resident pupils.

LIVERPOOL ROYAL SOUTHERN HOSPITAL (CLINICAL SCHOOLS).—Honorary Consulting Surgeons: Mr. Robert Hamilton and Dr. Henry G. Rawdon. Honorary Physicians: Drs. John Cameron, Wm. Carter, and Wm. Williams. Honorary Surgeons: Dr. Wm. Alexander, Mr. Robert Jones, and Dr. Geo. P. Newbolt. Consulting Pathologist: Professor R. W. Boyce. Lecturer on Practical Medicine: Dr. C. J. Macalister. Pathologist: Dr. F. H. Barendt. Medical Tutor and Bacteriologist: Dr. H. R. Jones. Demonstrator of Chemistry: Mr. Herbert E. Davies. Honorary Ophthalmic Surgeon: Mr. R. Williams. Honorary Aural Surgeon: Mr. C. G. Lee. Honorary Laryngologist: Dr. W. Permewan. Honorary Photographer (the x Rays Photography): Dr. C. Thurstan Holland. Honorary Dental Surgeon: Mr. J. Royston. House Surgeon: Mr. C. E. Morris. Junior House Surgeons: Dr. John Owen and Dr. M. A. Archdall. The hospital is situated within convenient distance of the School of Medicine and contains 200 beds. There are special wards for accidents and Diseases of Children, and there are also beds appropriated to the Diseases of Women. Clinical teaching is given in the hospital, and arrangements have been made to render it both thorough and systematic. The members of the staff visit the wards daily, and clinical lectures are given every week. Tutorial classes are also held each day at which the junior students are instructed in the methods of diagnosis and the seniors are prepared for their final examinations. The pathological department has a good laboratory attached in which the students receive practical instruction. Recently a bacteriological laboratory has been added, where students are able to obtain a practical knowledge of bacteriology in relation to medicine. In connexion with the hospital a course of instruction for gentlemen desirous of obtaining a Diploma in Public Health is given, and with this object a chemical laboratory under Mr. Herbert Davies, M.A. Camb., B.Sc. Lond., has been opened. In addition to the usual clinical and post-mortem clerkships, which are open to all students, the resident post of Ambulance Officer is awarded every three months to the student whom the board may consider most suited to hold it. A Scholarship of £20 is competed for annually, which has attached to it some clinical and pathological duties; and three prizes of £5 each are yearly offered for the best series of clinical reports. Fees: Perpetual £26 5*s*.; one year £10 10*s*.; six months £7 7*s*.; three months £4 4*s*. A limited number of resident pupils can be received. Terms (exclusive of fees for Hospital Practice), £15 15*s*. per quarter. The practice of the hospital is recognised by all examining bodies. For further particulars apply to the Dean, Mr. Robert Jones, 11, Nelson-street, Liverpool.

[2] No returns.

ROYAL INFIRMARY, Liverpool.—The buildings of the new Royal Infirmary were completed and occupied in 1890. They stand on the old site, adjacent to the college, but enlarged by the purchase of a fine frontage in Pembroke-place and of the street known as Pembroke-gardens. Externally, they form a handsome and imposing group of buildings, the general arrangement of which may be gathered from the plan at the beginning of the prospectus. Every available open-air space has been taken advantage of to secure good airing grounds for the patients, and the beauty of the buildings has been not a little enhanced by the numerous balconies, colonnades, and flat roofs adapted to the same purpose for both patients and resident staff. Internally, no point in modern sanitary science has been omitted. There are 295 beds exclusive of the Lock Hospital. The wards—some parallelograms, some circular—have floors of waxed oak blocks laid on an iron and cement substratum. Three operating theatres and a clinical lecture theatre have been provided. There is an electrical room, and provision for special kinds of baths. The out-patient department comprises rooms for the treatment and study of minor medical and surgical maladies, for diseases of the eye, skin, larynx, nose, and teeth, as well as a gynæcological department. There is also a Lock Hospital. A room has been allotted to the clinical tutors, in which they may keep their records, whilst each surgeon and physician has a private room in connexion with his wards, where his dressers and clerks may write up and tabulate cases and investigate morbid products. The pathological department, which is daily becoming of more importance in medical education, has had much pains expended upon it, so as to give proper facilities for the study of morbid anatomy. It is hoped that the facilities for clinical work will be such as not merely to enable the present students to learn the practical parts of their profession thoroughly, but to attract students from over-crowded institutions where the number of pupils is far in excess of the opportunities for the bedside study of disease. In no hospital in the country are the resident physicians and surgeons so comfortably lodged. Each is provided with a bedroom and a private sitting-room in addition to the music-room and dining-room, where all the seven residents meet in common; a Students' Club Room is also set aside for their exclusive use. James Barr, M.D., Secretary of Medical Board, 72, Rodney-street, Liverpool.

NORFOLK AND NORWICH HOSPITAL (220 beds).—Fees: £10 10*s*. for six months', £15 15*s*. for twelve months' medical and surgical practice. Pupils: non-resident. Consulting Physicians: Sir P. Eade, M.D., and Sir Frederic Bateman, M.D. Consulting Surgeons: Mr. W. Cadge, F.R.C.S., and Dr. Beverley. Physicians: Dr. Barton, Dr. Burton-Fanning, and Dr. Long. Surgeons: Mr. Williams, Mr. H. S. Robinson, and Mr. S. H. Burton. Assistant Surgeons: Mr. D. D. Day and Mr. H. A. Ballance. Dental Surgeon: Mr. R. Wentworth White. House Surgeon: Mr. H. Wyllys. House Physician: Mr. F. W. Borris. Secretary: Mr. Poole Gabbett.

NORTHAMPTON GENERAL INFIRMARY (established 1743; rebuilt 1793).—The number of beds is 160. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica and Practical Pharmacy. Non-resident pupils are taken at a fee of £10 10*s*.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 200 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 1912; out-patients, 10,069. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities

Digitized by Google

for acquiring a practical knowledge of the profession. Physician: Dr. A. M. McAldowie and Dr. S. King Alcock. Surgeons: Mr. W. D. Spanton and Dr. G. Stokes Hatton. Assistant Physicians: Mr. Hubert Nicholls and Mr. T. Treffry Cockill. Assistant Surgeons: Dr. Wheelton Hind and Reginald Alcock. Ophthalmic Surgeon: Mr. Herbert H. Folker. Assistant Ophthalmic Surgeon: Mr. J. F. Arlidge. Dental Surgeon: Mr. A. Baines. House Surgeon: Dr. W. C. Allardice. House Physician: Mr. W. E. L. Horner. Secretary: Mr. Ralph Hordley.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL (founded 1845; beds, 230).—A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards.

SUSSEX COUNTY HOSPITAL (190 beds).—During the year 1897 1624 in-patients have been treated. The total number of out-patient attendances on the books during 1897 was 33,309. This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed museum. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the Dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. Assistant Surgeon: Mr. Joseph Collier. Resident Medical Officers: L. W. Crowe, M.D., and J. C. Muir, M.B. Medical Officer at the Dispensary: C. G. Ashe, M.B. During 1897 there were 1275 in-patients, and 11,606 out-patients were under treatment at the Dispensary.

THE MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Cheetham-hill-road, Manchester.—The hospital is situated near the centre of the town and contains 70 beds. Out-patients are seen daily at 9.30 A.M. and the wards are visited at 11 A.M. Secretary, Mr. H. Teague, 38, Barton Arcade, Manchester.

SCOTLAND.

MEDICAL SCHOOLS WITH FULL CURRICULUM.[1]

EDINBURGH.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1300 students avail themselves each year of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

In accordance with the statutes of the University of Edinburgh, one-half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

The following Order of Study is recommended as a guide to the student for a five years' course, though not enjoined:—First Year: Biology, Physics, Anatomy, Practical Anatomy, Chemistry, and Practical or Analytical Chemistry. Second Year: Anatomy, Practical Anatomy, Physiology, Practical Physiology, Surgery, and Materia Medica—the last either in this or the Third Year—and Hospital. Third Year: Practice of Medicine, Clinical Surgery, Practical Pharmacy, Clinical Medicine, Pathology, and Hospital. Fourth Year: Surgery or Clinical Surgery, Midwifery and Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Operative Surgery, and Hospital. Fifth Year: Classes on Special Subjects, Hospital, and Dispensary Practice.

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have clerked in their wards for at least six months. Six Residentships are appointed during the year for a period of six months each. Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital. In all respects the students are taught under regulations similar to those at the University of Edinburgh and the other Universities of Scotland, and they receive similar certificates at the close of each session. Moreover, the University and College authorities in Edinburgh and the governing board of the school call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class. The courses on special non-qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally. A list of the classes and lecturers will be found below. Special courses of instruction for dental students and for women are also included in the curriculum of this school. The classes of the school are conducted in several separate buildings, such as at Surgeons' Hall, Minto House, Nicolson-square, New School and Surgeon-square.

Lecturers and fees.—Winter Session: Anatomy, Practical Anatomy, and Demonstrations, Drs. Ryland Whitaker and R. J. A. Berry (£3 5*s.* and £4 4*s.*); Chemistry (Practical, &c.), Dr. S. Macadam, Mr. King, Mr. I. Macadam, and Drs. Aitken and Readman*; Physiology (Institutes of Medicine), Dr. Noël Paton (£3 5*s.*); General Pathology, &c., Drs. Bruce, Russell, and Leith (£3 5*s.*); Botany, Mr. A. N. McAlpine;† Practice of Physic, Drs. James, Affleck, Bramwell, Gibson, Philip, Graham Brown, R. A. Fleming, and G. Lovell Gulland (£3 5*s.*); Surgery, Messrs. Caird, Hodsdon, Shaw Maclaren, Thomson, and Wallace (£3 5*s.*); Materia Medica, &c., Drs. Craig,† and Lockhart Gillespie (£3 5*s.*); Midwifery, &c., Drs. Hart, Murray, and Haultain (£3 5*s.*); Medical Jurisprudence, &c., Dr. Littlejohn and Dr. Aitchison Robertson (£3 5*s.*); Natural History, Mr. J. Arthur Thomson† (£3 5*s.*); Natural Philosophy, Dr. Turner (£3 5*s.*); Hospital Practice (Edinburgh Royal Infirmary): Physicians, Drs. Affleck, Smart, James, and Croom; Surgeons, Messrs. Duncan and Miller, Drs. Maclaren and MacGillivray (perpetual ticket, £12 12*s.*); Clinical Medicine, Drs. Affleck, Smart, James, Byrom Bramwell, and Croom (Diseases of Women) (£3 5*s*); Clinical Surgery, Dr. Maclaren, Dr. Macgillivray, Mr Cotterill, and Mr. Cathcart (£3 5*s.*); Diseases of Children, the staff of the Sick Children's Hospital (£2 2*s.*); Diseases of the Skin, Drs. Jamieson† and Stirling† (£2 2*s.*); Diseases of the Chest, Dr. Philip† (£2 2*s.*); Vaccination, Drs. Husband,† Buist,† and Cadell (£1 1*s.*); Diseases of Ear, Nose, and Throat, Drs. Kirk and Duncanson,† (£2 2*s.*); Diseases of the Eye, Dr. G. Mackay,† and Dr. Sym† (£2 2*s.*); Gynæcology, Drs. Croom (Systematic), Brewis (Clinical), and Berry Hart (Advanced) (£2 2*s.*); Summer Session: Practical Anatomy and Demonstrations, Drs. Ryland Whitaker and R. J. A. of Medicine, Drs. Bramwell, Gibson, and Philip (£3 3s.); Medical Electricity, &c., Dr. Turner (£2 2s.); Diseases of the Circulation, Dr. Gibson (£2 2s.).

Special Classes for Women, Winter Session: Practical Anatomy and Demonstrations, Drs. Ryland Whitaker and Hardie (£4 4s.); Chemistry (Lectures and Practical), Mr. Ivison Macadam and Dr. Aitken (£3 5s. and £3 3s.); Practice of Physic, Drs. Philip and Graham Brown (£3 5s.); Surgery, Mr. Thomson and Mr. McLaren (£3 5s.); General Pathology, Dr. Russell (£3 5s.); Physiology (Institutes of Medicine), Dr. Noël Paton (£3 5s.); Practical Pathology, Dr. Bruce, &c. (£3 5s.); Materia Medica, &c., Dr. Craig (£3 5s.); Clinical Medicine, Dr. Bramwell, Royal Infirmary (£3 5s.); Clinical Surgery, Royal Infirmary (£3 5s.); Physics, Dr. Dawson Turner (£3 3s); Biology, Mr. Thomson and Mr. Turnbull (£3 3s.); Diseases of Children, the staff of the Sick Children's Hospital and Dr. Cumming (£2 2s.); Vaccination, Dr. Husband and Mr. Cadell £1 1s.); Practical Gynæcology, Dr. Brewis (£2 2s.). Summer Session: Practical Anatomy, Dr. Ryland Whitaker and Mr. Hardie (£2 2s.); Practical Chemistry, Mr. Ivison Macadam and Dr. Aitken (£3 3s); Materia Medica, &c., Dr. Craig (£3 3s.); Operative Surgery and Surgical Anatomy, Mr. Alexis Thomson and Mr. McLaren (£3 3s.); Materia Medica and Therapeutics, vacant (£3 3s.); Midwifery and Diseases of Women, Drs. Sophia Jex-Blake and R. Milne Murray (£3 5s.); Medical Jurisprudence and Public Health, Dr. Harvey Littlejohn (£3 5s.); Clinical Medicine and Clinical Surgery, Royal Infirmary (£3 5s.); Practical Physiology and Histology, Dr. Paton (£3 3s.); Practical Pathology, Dr. Russell (£3 3s.); Biology, Mr. Arthur Thomson and Mr. Turnbull (£3 3s.); Physics, Dr. Dawson Turner (£3 3s.); Diseases of Children, Mr. Bell, Dr. Burn-Murdoch, and Dr. Cumming (£2 2s.); Ophthalmology, Dr. Mackay (£2 2s.); Insanity, Dr. Macpherson (£2 2s.); Practical Gynæcology, Dr. Brewis (£2 2s.).

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £115, which is payable by instalments during the period of study.

Further particulars regarding the school, also its calendar, may be had on application to Mr. R. N. Ramsay, the Secretary, 24, Forrest-road, Edinburgh.

* Lectures, £3 5s.; Practical, £3 3s.; Analytical, £2 a month, or £5 for three months. † Also in Summer Session. ‡ Also in Winter Session. § Practical, £3 3s.; Analytical, £2 a month, or £5 for three months.

N.B.—Where two or more lecturers appear as teaching the same subjects their lectures are not conjoined, but each gives an independent course.

GLASGOW.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Glasgow.—This medical school was founded in the year 1800. It has given twelve professors to the University of Glasgow, of whom two at present hold office. The following courses are given, which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions):—In winter: Anatomy, Professor A. M. Buchanan, M.A., M.D.; Chemistry, Professor J. Robertson Watson, M.A.; Physics, Professor Peter Bennett; Zoology, Professor Geo. Bell Todd, M.B.; Physiology, Professor W. Ernest Thomson, M.A., M.D.; Surgery, Professor T. Kennedy Dalziel, M.B.; Practice of Medicine, Professor Samson Gemmell, M.D.; Midwifery and Diseases of Children, Professor John Edgar, M.A., B.Sc., M.D.; Materia Medica, Professor R. Barclay Ness, M.A., M.B.; Botany, Professor B. G. Cormack, M.A., B.Sc.; Ophthalmic Medicine and Surgery, T. Spence Meighan, M.D.; Aural Surgery, James Erskine, M.A., M.B.; Diseases of Throat and Nose, John Macintyre, M.B.; Hygiene and Public Health, Joseph Carroll, M.B., D.P.H. In summer: Anatomy, Practical Anatomy and Osteology, Practical Chemistry, Physics, Zoology, Practical Materia Medica and Pharmacy, Practical Physiology, Operative Surgery, Botany, Ophthalmic Medicine and Surgery, also Medical Jurisprudence, Professor R. M. Buchanan, M.B., and Mental Diseases, Dr. Carswell; Hygiene and Public Health, and Aural Surgery. The Chemical Laboratory is open daily from 10 to 6. The Dissecting-room is open in winter from 9 A.M. to 6 P.M., and in summer from 6 A.M. to 6 P.M. The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted. The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them. The Dissecting-room is provided with a complete series of dissected specimens, mounted in plaster of Paris, illustrating the anatomy of the human body. Candidates for the licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of it, and four minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Physiology, Practical Pharmacy, Public Health, and Operative Surgery. There are also provided a large library and reading-room and a students' recreation-room.

Fees.—For each of the above courses of Lectures (Anatomy, Chemistry, Botany, Zoology, Practical Physiology, Practical Pharmacy, and Mental Diseases excepted), first session, £2 2s.; second session, £1 1s. Anatomy Class Fees: Winter, first session (including Practical Anatomy), £4 4s.; second session (including Practical Anatomy), £4 4s.; third session, £2 2s. To those who have had the necessary courses of Practical Anatomy the fee will be £1 1s. Summer, Lectures and Practical Anatomy, £2 12s. 6d.; Lectures alone, £1 11s. 6d.; Practical Anatomy alone, £1 1s.; Osteology and Practical Anatomy, £2 12s. 6d.; Osteology alone, £1 11s. 6d. Chemistry Fees: First course, £2 2s.; second course, £2 2s. Practical Physiology Fees.—First course, £2 2s. Second course, £2 2s. Practical Materia Medica and Pharmacy Fees.—First course, £2 2s. Second course, £2 2s. Botany fee, £1 11s. 6d. Zoology, fee £1 11s. 6d.

Digitized by Google

Mental Diseases, £1 1s. Matriculation Fees: Winter, 10s. to those taking out two or more classes; 5s. to those taking out only one class. The fee of 10s. represents a combined fee for the winter and summer sessions. Summer, 5s., except to those who have paid a fee of 10s. for the Winter Session. Students who have attended classes at other schools, and who desire to pursue their studies at Anderson's College Medical School, will be admitted to such classes as they may have attended elsewhere at the reduced fees.

Royal Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; Pathology, both courses, £3 3s. Vaccination Fee, £1 1s.

Western Infirmary. — Fees: Hospital Practice and Clinical Instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £7 7s.; three months, £4 4s. Pathology, first course, £3 3s.; second course, £2 2s. Practical Pathology, first course, £3 3s., second course, £2 2s. Vaccination Fee, £1 1s.

Eye Infirmary.—Fee: Hospital Practice and Clinical instruction, six months, £1 1s.

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions); by the Royal Colleges of Physicians of London and Edinburgh; by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland; by the Royal College of Physicians of Ireland; by the Faculty of Physicians and Surgeons of Glasgow; by the Society of Apothecaries, London; and by the Army, Navy, and East India Boards. Communications relating to the Medical School to be addressed to The Secretary of the Medical Faculty, Anderson's College Medical School, Dumbarton-road, Partick, Glasgow. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Alexander Mackay, LL.D., Educational Institute Office, 40, Princes-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Alexander Duncan, LL.D., Faculty Hall, 242, St. Vincent-street, Glasgow. Communications relating to the Dental School to be addressed to Mr. D. M. Alexander, 97, West Regent-street, Glasgow.

The Kerr Bursary in Anatomy (value £10) is open to students of the Junior Anatomy Class during Winter Session 1898-99.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This College was incorporated in 1889. The Glasgow Royal Infirmary was founded in 1791. The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary. The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements. Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories. The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest general and special hospitals in the kingdom. It has nearly 600 beds, and will almost immediately have considerably over 600. It has special wards for Diseases Peculiar to Women, for Venereal Diseases, Erysipelas, Burns, and Diseases of the Throat and Nose. At the Dispensary special advice and treatment are given in diseases of the Eye, Ear, Teeth, and Skin, Women, Throat and Nose, in addition to the large and varied number of ordinary medical and surgical cases—over 46,000 per annum—which in a great industrial centre daily require attention. Students of the College and Hospital get the benefit of dispensary experience free of charge. All appointments are open. There are five Physicians' and seven Surgeons' Assistants, who board in the hospital free of charge and act in the capacity of House Physicians and House Surgeons. These appointments are made for six months, and are open to gentlemen who have a legal qualification in Medicine or Surgery, and preference is given to the students of this College and Hospital. Clerks and Dressers are appointed by the Physicians and Surgeons. From the large number of cases of acute disease and accidents of varied character received into this hospital these appointments are very valuable. In the Pathological Department assistants are also appointed. The session will open with an address on Wednesday, Oct. 20th, at the College buildings.

Ophthalmic Department.—The Ophthalmic Institution in West Regent-street having been amalgamated with the Royal Infirmary the usefulness of this department is very much increased, and greater opportunities are afforded to students for the practical study of Diseases of the Eye. Dr. Ramsay, the ophthalmic surgeon, attends the Royal Infirmary every Monday, Wednesday, and Friday at 12 noon, and daily at the Institution in West Regent-street from 1 to 2 o'clock. Students can attend both without payment of any additional fee. Lectures are delivered twice a week during the winter session. Fee for the course, £2 2s.

The fee for each class is £2 2s., except for Anatomy, which is £4 4s., Pathology £4 4s., Zoology £4 4s., Botany £3 3s., Practical Physiology, £3 3s., and for Physics, which is £2 4s. 6d., and certain extra classes, for which the fee is £1 1s. The hospital fee (including clinical lectures) is £21 for a perpetual ticket. The classes in St. Mungo's College and in the Glasgow Royal Infirmary are for male students exclusively. Further particulars can be obtained in the Calendar of the College (price 1s.), or syllabus which can be obtained free on application to the Dean, 86, Castle-street, Glasgow. Remittance should accompany application.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is situated in University-avenue, close to the University and Western Infirmary, in which latter students obtain their Hospital Practice and Clinical Lectures. Lectures and Demonstrations are given on Chemistry, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, and on the Eye.

Class Fees.—For each course of Lectures the fee is £2 2s., or in some cases £1 1s. There is no matriculation fee.

QUEEN MARGARET COLLEGE, University of Glasgow.—Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs. John Elder. In 1890 a School of Medicine for women was added to its Arts Faculty. In 1892, when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs. Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only. The College then became the women's department of the University of Glasgow; its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The number of students enrolled in session 1897-8 was 267, of whom 86 were studying medicine, and the rest arts or science. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University. Twenty-seven women have now taken the degree of M.B., C.M. or M.B., Ch.B. of the University of Glasgow. Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals. By a gift of £5000 lately granted for the purpose by the Bellahouston Trust the University Court was enabled to add to the College a large new building for the study of Anatomy and Physiology, which was opened in October, 1895. The Arthur Scholarship is open every third year to students of first year entered the October previously to the award; the George Grant Bursary has been held by a woman student, and there are other Bursaries open in Arts as well as in Medicine; and the Universities Commissioners have issued an ordinance making regulations for the admission of women to certain University bursaries, scholarships, and fellowships. A house of residence for the students of the College coming from a distance was opened by the Queen Margaret Hall Co., Limited, in October of 1894.

DUNDEE.

UNIVERSITY COLLEGE, Dundee (University of St. Andrews).—The classes of this College qualify for graduation in the University of St. Andrews and are recognised by the other Scotch Universities; they also qualify for the degrees of the

Digitized by Google

University of London and the Royal University of Ireland and for the Licences of the Royal Colleges. Equipment has in the past been provided for the first three years of the medical curriculum, but arrangements are at present being made for the inauguration of the complete course in October, 1898. The Royal Infirmary of Dundee contains about 300 beds, and the clinical instruction and hospital attendance in its wards are recognised by the various degree-giving and licensing bodies. In all the special departments of study facilities are offered to senior students.

Scholarships:—First year: (*a*) Three Armitstead Scholarships of £20 each, tenable for one year. (These Scholarships were founded and endowed in 1883 by George Armitstead, Esq., M.P.) (*b*) Three Scholarships of £15 each, tenable for one year. Second year: Three Armitstead Scholarships of £20 each, tenable for one year, to be awarded to day students entering upon their second year. Candidates must have attended not less than two regular courses at the College during the year immediately preceding the competition. (*c*) Bute Bursary, founded in 1893 by the Most Honourable the Marquess of Bute, K.T.; this bursary consists of the free proceeds of £1000. (*d*) Two bursaries of the annual value of £25, and tenable for three years, either "at University College, Dundee, or at any Scottish University."

Fees.—Chemistry, £3 3*s*.; Prof. James Walker, D.Sc. Practical Chemistry: Winter £3 3*s*., Summer £2 2*s*.; Prof. James Walker, D.Sc. Physics: Winter £3 3*s*., Prof. Kuenen, Ph.D., M.A. Zoology, £3 3*s*., Prof. D'Arcy W. Thompson, M.A. Botany, £3 3*s*., Prof. Geddes. Anatomy, £3 3*s*.; Prof. Yule Mackay, M.D. Practical Anatomy: Winter £3 3*s*., Summer £2 2*s*.; Prof. Yule Mackay, M.D. Physiology, £3 3*s*.; Prof. E. W. Reid, B.A., M.B. Practical Physiology and Histology, £2 2*s*.; Prof. E. W. Reid, B.A., M.B. Surgery. £3 3*s*.; Prof. D. MacEwan. Operative Surgery, £3 3*s*.; Prof. MacEwan. Practice of Medicine, £3 3*s*.; Prof. A. N. Stalker. Clinical Medicine, Prof. Stalker and Dr. Mackie Whyte. Clinical Surgery, Prof. MacEwan and Dr. Greig. Hospital fee, £2 2*s*.; Dispensary, £2 2*s*. Pathology, £3 3*s*. Materia Medica and Therapeutics, £3 3*s*. Midwifery. £3 3*s*. Medical Jurisprudence and Public Health, £3 3*s*.; Dr. Templeman. The Lectures and Classes for the winter session will commence on Wednesday, Oct. 5th.

ROYAL INFIRMARY.—The Infirmary contains 286 beds, including special wards for the Diseases of Children, Eye, and Lock cases. In addition, there were during last year 7798 out-patients and 6629 home patients. The Royal Infirmary offers exceptional facilities for practical work to students. Three qualified Resident Assistants and Clinical and Pathological Assistants are appointed as vacancies occur. Appointments: Three qualified Resident Medical Assistants are appointed every six months. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological department. There is in connexion with the hospital course a class of Minor Surgery and Bandaging, conducted by the Assistant Surgeons, and a class of Practical Pharmacy and Materia Medica held at the Dispensary. Full information can be obtained from Dr. H. E. Fraser, Medical Superintendent.

ROYAL ASYLUM.—Lectures on Mental Diseases and clinical instruction in connexion with University College, Dundee (University of St. Andrew's), are given at the University and at the Royal Asylum. There are two paid qualified Resident Assistants and two unpaid Resident Clinical Assistants. Last Summer Session began April 19th, 1898. Prize-winners at lectures: (1) Miss Ann Mercer Watson; (2) Miss Laura Stewart Sandeman. Dr. Richardson, Medical Assistant, resigned; F. W. Gardiner, M.B., C.M., appointed in his place.

ABERDEEN.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains, with hospital attached to main institution and Agricultural Branch, about 820 beds. Medical Superintendent: Dr. William Reid. Assistant Physicians: Dr. W. R. Matthews and Dr. Moir. Joint Secretaries: Mr. W. Carnie and Charles M. Brown. Clinical instruction is given to students during three months in summer.

ABERDEEN ROYAL INFIRMARY.—Contains over 200 beds. Consulting Physicians: Drs. P. Blaikie Smith and James Rodger. Physicians: Drs. Angus Fraser, Professor Finlay, and George M. Edmond. Assistant Physicians: Drs. John Gordon, A. H. Lister, and Ashley W. Mackintosh. Consulting Surgeon: Dr. J. C. O. Will. Surgeons: Professor A. Ogston, Drs. R. J. Garden and J. McK. Booth. Assistant Surgeons: Drs. J. S. Riddell, W. Sinclair, and J. Marnoch. Ophthalmic Surgeon: Dr. C. H. Usher. Gynæcologist: Professor W. Stephenson. Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. G. Duncan. Dental Surgeon: Dr. W. H. Williamson. Anæsthetist: Dr. J. J. Y. Dalgarno. Assistant ditto: Dr. H. M. W. Gray. Medical Electrician: Dr. J. R. Levack. Clinical Registrar: Dr. W. R. Pirie. Medical Superintendent: Charles Angus, M.B. Joint Treasurers and Secretaries: Mr. W. Carnie and Mr. Charles M. Brown.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ROYAL INFIRMARY, Edinburgh.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, and the Skin, and also to cases of Incidental Delirium or Insanity. Three wards are specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s*.; six months, £4 4*s*.; three months, £2 2*s*.; monthly, £1 1*s*. Separate payments amounting to £12 12*s*. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident physicians and surgeons are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologists.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital, which has been recently built, contains over 100 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. A limited number of Clinical Clerkships are obtainable. Full particulars can be obtained from the Registrar at the hospital.

EDINBURGH EYE, EAR, AND THROAT INFIRMARY, 6, Cambridge-street, Lothian-road.—The Infirmary has been entirely re-arranged and greatly improved by recent structural alterations and the electric light introduced; also the electric power is used for illumination and cauterising purposes in all departments. Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon for out-door Ear Patients; and Tuesdays and Fridays at 4 P.M. for out-door Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell, F.R.C.S.E. Surgeons: Dr. J. J. Kirk Duncanson, F.R.C.P.E. and F.R.S.E.; Dr. G. Hunter Mackenzie; Dr. William George Sym, F.R.C.S.E.; Dr. Alexander Black, F.R.C.P.E.; and Dr. Malcolm Farquharson. Dental Surgeon: Mr. G. W. Watson, L.D.S. Treasurer and Secretary: Mr. J. P. Waton, W.S., 13, Hill-street.

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for

Digitized by Google

urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, at 2 P.M., by Dr. Barr and assistants. Course of Lecutres and Clinical Instruction given during winter months by Dr. Barr.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Ten resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year; for six months, 7 guineas; and for three months, 4 guineas.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow, situated at Garnet Hill.—This hospital was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 80 beds for non-infectious cases only. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888. Students may be enrolled at any time. Fee £1 1*s.* per annum, admitting to both Hospital and Dispensary. Particulars on applying to the House Surgeon, 45, Scott-street, Garnet-hill, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (30 beds).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 476; out- or dispensary patients, 2634. Operations on Wednesdays and Saturdays. Consulting Surgeon: D. N. Knox, M.B., C.M., F.F.P.S.G. Acting Surgeon: A. Maitland Ramsay, M.D. Assistant Surgeon: John Rowan, M.B., C.M. Assistant Surgeon and Pathologist: H Walker, M.B., C.M. House Surgeons: H. W. Thomson, M.B., C.M.; Malcolm Watson, M.B., C.M. This institution has recently been amalgamated with the Glasgow Royal Infirmary, of which it forms an integral part.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary. The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves. The average number of new patients for the last ten years has been 13,842, and the total number of cases treated in 1897 was 20,057. The Medical Staff is as follows:—Senior Surgeon: Thomas Reid, M.D. Surgeons: Thomas S. Meighan, M.D., and A. Freeland Fergus, M.D. William Robertson, M.D. Andrew Wilson, M.B., C.M., and James Hinshelwood, M.A., M.D. Pathologist: Leslie Buchanan, M.B., C.M. House Surgeon: H. Wright Thomson, M.B., C.M. Assistant House Surgeon: Arthur D. Ketchen, M.B., M.R.C.S. Clinical Assistants: A. Lewis M'Millan, M.B., C.M.; W. Ernest Thomson, M.A., M.D.; Henry L. G. Least, M.D.; W. Cochrane Murray, M.B., C.M.; Leslie Buchanan, M.B., C.M.; Brownlow Riddell, M.B.

Regulations as to Attendance of Students.—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1*s.*, twelve months £2 2*s.* (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the surgeon whose clinique they are attending when he visits his patients. They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation. Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Secretary: William George Black, 88, West Regent-street.

IRISH SCHOOLS OF MEDICINE.[1]

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each. Two are tenable by matriculated students, of the first, second, third, fourth, and fifth years of their course respectively. The examinations for Scholarships take place at the commencement of the session. Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c., of the Royal University of Ireland are also open to students. Lectures in Medicine at Queen's College, Belfast, will commence on Oct. 18th and end on March 31st. The Summer Session will begin on May 1st. Clinical instruction is given at the Royal Hospital. The Ulster Hospital for Diseases of Women and Children, the Maternity Hospital, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Hospital for Sick Children, and the District Lunatic Asylum are open to students. A pamphlet containing full information can be had free on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological, toxicological, and pathological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are open to students in their first four years and the Blayney Scholarship and a Senior Exhibition to students in their fifth year.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months, £8 8*s.* Summer, three months, £5 5*s.*

Staff.—Physicians: James Little, M.D., M.R.I.A.; Wallace Beatty, M.D., F.R.C.P.I.; H. T. Bewley, M.D., F.R.C.P.I. Surgeons: F. T. Heuston, M.D., F.R.C.S.I.; J. H. Scott, M.B., F.R.C.S.I.; T. E. Gordon, M.B., F.R.C.S.I. Obstetric Surgeon: W. J. Smyly, M.D., F.R.C.P.I. Ophthalmic Surgeon: H. R. Swanzy, M.B., F.R.C.S.I. Pathologist and Bacteriologist: J. Alfred Scott, M.D., F.R.C.S.I. Medical and Surgical Registrar: G. Peacocke, M.D., B.Ch. House Surgeon: T. Douglas Good, M.B., B.Ch.

A resident surgeon is elected yearly, and three resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Obstetric Medicine will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical

[1] For Scholarships see page 648 et seq.

Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology and Gynæcology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Mr. F. T. Heuston.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds, and consists of two divisions, one of which is devoted to lying-in cases, and the other to the treatment of the diseases peculiar to women. The maternity department is one of the largest in Ireland, 3000 cases being annually treated either as intern or extern patients. A regular course of lectures is delivered in the hospital, and clinical instruction is given daily at the bedside. There are two large dispensaries connected with the institution, at one of which instruction is given on the General Diseases of Women and Children, and in the other on the Diseases Peculiar to Women. There is accommodation for a limited number of intern pupils, who enjoy exceptional advantages of acquiring a practical knowledge of this branch of their profession. Two Resident Pupil Midwifery Assistants and one Clinical Clerk are elected half-yearly from among the pupils of the hospital. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. Fees (six months' course): extern pupils, 8 guineas, half payable in advance; intern pupils, 18 guineas for six months' residence. If pupils enter as interns by the month the fees are £4 4*s.* for first month, and £3 3*s.* for each succeeding month. Intern pupils enjoy very special advantages, which can be learned on application. Registration fee on entrance, 10*s.* 6*d.* Students can enter for attendance at any time. Further particulars may be had on application to the Master or the Registrar at the hospital.

SIR PATRICK DUN'S HOSPITAL.—Fees for attendance of students—nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* The hospital is open to extern students as well as to the students of Trinity College, and the certificates are recognised by all the licensing bodies in the kingdom. Dr. Taylor, Secretary to the Medical Board, will give any further information.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical and Surgical Resident Pupils and Clinical Clerks and Dressers are appointed every six months, and a House Surgeon is elected annually. A prospectus giving the complete arrangements for the Medical and Surgical classes for the coming session may be obtained from the Secretary of the Medical Board, R. Glasgow Patteson, F.R.C.S., 20, Lower Baggot-street, Dublin.

MATER MISERICORDIÆ HOSPITAL, Dublin. — Consulting Physician: Sir Francis R. Cruise. Physicians: Sir Christopher Nixon, Drs. Joseph Redmond, Michael Boyd, and John Murphy. Assistant Physician: Dr. Martin Dempsey. Medical Registrar: Dr. John O'Donnell. Surgeons: Messrs. Patrick Hayes, Charles Coppinger, Arthur Chance, and John Lentaigne. Assistant Surgeon: Mr. Hugh Blaney. Obstetric Physician: Dr. Thos. More Madden. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. Daniel Corbett, jun. Pathologist: Dr. Edmond McWeeney. Anæsthetist and Surgical Registrar: Dr. Michael O'Sullivan. House Physician: Dr. Farnan. House Surgeons: Messrs. Coppinger, Blayney, Keller, and O'Regan. This hospital, the largest in Dublin, at present containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Instruction at the bedside will be given by the Physicians and Surgeons at 9 A.M. daily. Clinical Instruction will commence on Monday, Oct. 3rd, at 9 A.M. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays, and Saturdays at 11 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, &c. Instruction will be given on Pathology and Bacteriology. Junior Appointments: A House Physician and four House Surgeons will be appointed annually. Eight resident pupils will be elected from the most attentive of the class to hold office for six months. For the current session the elections will take place in the first week of November and in the first week of May. Dressers and Clinical Clerks will be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes: One Gold and one Silver Medal will be offered for competition annually in the subject of Medicine, and one Gold and one Silver Medal in the subject of Surgery. Junior Leonard Prizes: One prize value £3 and one prize value £2 will be awarded in Medicine, and one prize value £3 and one prize value £2 will be awarded in Surgery. They will be awarded on the aggregate of marks gained for Reports of Cases and at a Clinical Examination to be held at the close of the summer session. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training School and Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Arthur Chance, F.R.C.S., 90, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Dr. Joseph Redmond, 41, Merrion-square, E., Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each year, and are paid for their services. Clinical Clerks: Five Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students as formerly, but also to those who are qualified in Medicine or Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to Sir W. Thomson, F.R.C.S., Treasurer, 54, Stephen's-green East; or to J. O'Carroll, M.D., Hon. Sec., 43, Merrion-square, Dublin.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity and a Dispensary for Diseases Peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in Midwifery. Accommodation is provided for a limited number of intern pupils.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 200 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions, and affords exceptional advantages for clinical instruction. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways. There is a ward entirely devoted to Venereal Disease, a detached building for Fever Cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Eye, Ear, and Teeth.

The hospital is visited daily at 9 A.M. by the physicians and surgeons. The wards are also visited by the resident surgeon each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s*; three months, £5 5*s.* Dressership: £10 10*s.* each three months. Further information may be obtained from the Resident Surgeon or from R. A. Hayes, M.D., Hon. Sec., 82, Merrion-square South.

	No. 2.	£40 per annum.	2 years.	By first place with distinction in PHYSIOLOGY AND HISTOLOGY at July Intermediate M.B. Examination.	Ditto.
	No. 3.	£30 per annum.	2 years.	By first place with distinction in ORGANIC CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
	No. 4.	£30 per annum.	2 years.	By first place with distinction in MATERIA MEDICA and PHARMACEUTICAL CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
	University Scholarship in Medicine.	£50 per annum.	2 years.	By first place with distinction in MEDICINE at M.B. Honours Examination.	
	University Scholarship in Obstetric Medicine.	£30 per annum.	2 years.	By first place with distinction in OBSTETRIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Forensic Medicine.	£30 per annum.	2 years.	By first place with distinction in FORENSIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Surgery.	£50 per annum.	2 years.	By first place with distinction in B.S Honours Examination.	
ST. BARTHOLOMEW'S MEDICAL SCHOOL	Entrance Scholarships. No. 1.	£75.	...	Open Competitive Examination in PHYSICS and CHEMISTRY.	Full Course at St. Bartholomew's Hospital.
	,, No. 2.	£75.	...	Open Competitive Examination in BIOLOGY and PHYSIOLOGY.	Ditto.
	,, No. 3	£150.	...	Open Competitive Examination in PHYSICS, CHEMISTRY, and BIOLOGY.	Ditto.
	Preliminary Scientific Exhibition.	£50.	...	Open Competitive Examination in PHYSICS, CHEMISTRY, and BIOLOGY.	Ditto.
	Jeaffreson Exhibition.	£20.	...	Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, FRENCH, or GERMAN.	None.
	Shuter Scholarship.	£50.	...	Competitive Examination among Cambridge Graduates in ANATOMY, PHYSIOLOGY, and MATERIA MEDICA.	None.
	Junior Scholarships.				
	,, No. 1.	£30.	...	Competitive Examination among Students in ANATOMY and BIOLOGY.	None.
	,, No. 2.	£20.	...	Ditto.	None.
	,, No. 3.	£25.	...	Competitive Examination in CHEMISTRY, PHYSICS, and HISTOLOGY.	None.
	,, No. 4.	£15.	...	Ditto.	None.
	Senior Scholarship.	£50.	....	Competitive Examination among Students in ANATOMY, PHYSIOLOGY, and CHEMISTRY.	Study at St. Bartholomew's Hospital.
	Kirkes Scholarship.	£30 and Medal.	....	Competitive Examination among Students in CLINICAL MEDICINE.	
	Brackenbury Scholarships.				
	,, No. 1.	£39.	...	Competitive Examination among Students in MEDICINE.	
	,, No. 2.	£39.	...	Competitive Examination among Students in SURGERY.	
	Lawrence Scholarship.	£42 and Medal.	....	Competitive Examination among Students in SURGERY, MEDICINE, and MIDWIFERY.	None.
	Sir Geo. Burrows Prize.	£10 10s.	...	Competitive Examination in PATHOLOGY among Students.	
	Skynner Prize.	£15.	...	Competitive Examination in REGIONAL and MORBID ANATOMY among Students.	
	Matthews Duncan Medal and Prize.	£20.	...	Competitive Examination among Students in MIDWIFERY and GYNÆCOLOGY.	None.
	Research Studentship in Pathology.	£100.	...	By Election, on the recommendation of the School Committee.	Research Work at St. Bartholomew's Hospital.
CHARING CROSS HOSPITAL AND COLLEGE	Entrance Scholarships, open to students at the commencement of curriculum.				
	Livingstone.	100 guineas.	...	The Livingstone and Huxley Scholarships are awarded annually at the commencement of each Winter Session, after a competitive examination in the following groups of subjects: — (1) ENGLISH, including LANGUAGE, HISTORY, and GEOGRAPHY; (2) Any two of the following four languages —LATIN, GREEK, FRENCH, and GERMAN; (3) MATHEMATICS,	Open to all general students.
	...	60 ,,	...		Open to all general students.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
MASON UNIVERSITY COLLEGE BIRMINGHAM.	Ingleby Scholarships (1 or more).	£10 to £15.	1 year.	....	Candidates must have spent first two years of curriculum at the College.
	Sydenham Scholarship.	£10 10s. per annum.	3 years.	Award of Council to orphan sons of Medical Practitioners.	
	Sands Cox Scholarship.	£10 10s. per annum.	3 years.	Competitive Examination among sons of Medical Practitioners under eighteen years of age in ARTS SUBJECTS.	
	Queen's Scholarship.	£10 10s. per annum.	3 years.	Open Competitive Examination in ELEMENTARY SCIENCE, with a Modern Language.	
	Dental Scholarship.	£7 17s. 6d.	2 years.	Open Competitive Examination in subjects learned during apprenticeship.	
VICTORIA UNIVERSITY ...	Gilchrist Scholarship.	£50.	3 years.	Awarded annually to the candidate who shall stand highest at the June preliminary examination of the Victoria University provided that he pass in the first division.	Candidates must be over 18 years of age on July 1st in the year of competition.
	University Scholarship in Medicine.	£50.	1 year.	Awarded annually on the results of the second examination for the degrees of M.B. and Ch.B.	
OWENS COLLEGE, MANCHESTER	General Entrance Scholarships.	....	....	....	Open to candidates above 16 and under 20 years of age.
	Rogers.	£40.	2 years.	Subjects: GREEK, LATIN TRANSLATIONS AT SIGHT, and PROSE COMPOSITION.	
	Seaton.	£40.	2 years,	Subjects: GREEK, LATIN TRANSLATIONS AT SIGHT, and PROSE COMPOSITION.	
	Dalton.	£40.	2 years.	Subjects: EUCLID, ALGEBRA, TRIGONOMETRY, GEOMETRY, and CONIC SECTIONS.	
	Cartwright.	£35.	3 years.	Ditto.	
	Hulme.	£35.	3 years.	Subjects: ENGLISH LANGUAGE and LITERATURE, HISTORY, GEOGRAPHY, and (LATIN, GREEK, FRENCH, or GERMAN, any two subjects).	
	James Gaskill.	£40.	2 years.	MATHEMATICS and CHEMISTRY.	
	Manchester Grammar School	£18.	3 years.	MATHEMATICS, ENGLISH ESSAY with CLASSICS and PHYSICAL SCIENCE in alternate years.	
	Kay-Shuttleworth	£30.	3 years.	Subjects as in James Gaskill Scholarships.	Pupils of Sedbergh, Giggleswick, or Burnley Grammar School.
	Theodores Exhibition.	£15.	1 year.	Subjects: FRENCH and GERMAN.	Successful candidates are required to enter for a regular University course.
	Robert Platt Physiological Scholarship.	£50.	2 years.	Subjects: PHYSIOLOGY and COMPARATIVE ANATOMY.	Open to Candidates whether or not previously students of the College.
	Dauntesey Medical Scholarships (two).	£35 each.	1 year.	Subjects: ZOOLOGY, BOTANY, and CHEMISTRY.	These Scholarships are open to all students preparing for a Medical Course who shall not have attended Lectures or Laboratory Courses on Human Anatomy or Physiology, or a purely Medical or Surgical Course in the Owens College or any other Medical School in the United Kingdom. Candidates must not be more than 25 years of age on October 1st of the year of competition. Scholars must immediately on election enter for a full course of medical studies.
	Robert Platt Exhibitions (two).	£1 each.	....	....	First and second years' students in Physiology.

NOTE.—*St. Mary's Hospital.*—A Gold Medal in Clinical Medicine has been founded this year for Fifth-year Students by Dr. W. B. Cheadle.

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

ENGLAND.

THE following recommendations, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council in 1896.[1] The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health, or State Medicine; (2) every candidate shall have produced evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory approved of by the body granting the qualification; (3) every candidate shall have produced evidence of having for six months practically studied the duties of out-door sanitary work either under a medical officer of health who is a teacher in public health in a recognised school, or under the medical officer of health of a county or of a single sanitary district of 50,000, or a combination of districts of 35,000 inhabitants in England, or in one or more districts of 30,000 in Scotland or Ireland; (4) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (5) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act [England and Wales], 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previously to Aug. 13th, 1888, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board, the same person may be appointed medical officer for two or more districts.

London University.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' out-door sanitary work. Certificates will be received from the holder of any public health office directly or indirectly subject to control by a Secretary of State or a Government Department. If a candidate have studied State Medicine for two years or have studied State Medicine for one year and have held for a period of two years the position of medical officer of health in any sanitary district, or without having studied State Medicine have held for a period of three years the position of medical officer of health in any sanitary district, he will be eligible for the examination.

Cambridge University.—Examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held in Cambridge, beginning on the first Tuesday in April and in October, and ending in the following week. Any person whose name is on the Medical Register is eligible as a candidate for this examination: Provided (*a*) he be in his twenty-fourth year at least when he presents himself for the first part of the examination, and have attained twenty-four years of age before he presents himself for the second part; (*b*) a period of not less than twelve months shall have elapsed between the time when he first obtained a registrable qualification and the time when he presents himself for either part of the examination; (*c*) he produce evidence of having, before or after obtaining a registrable qualification, attended the clinical practice of a hospital for infectious diseases approved by one of the licensing bodies recognised under the Medical Acts; (*d*) he produce evidence of having, after obtaining a registrable qualification attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible to man; (*e*) he produce evidence of having, after obtaining a registrable qualification, practically studied for six months the duties of out-door sanitary work under the medical officer of health of a county or large urban district, unless he have himself held an appointment as medical officer of health under conditions not requiring a special sanitary diploma. The provisions (*b*), (*c*), (*d*), (*e*) are not to apply to (*a*) candidates whose names shall have been placed on the Medical Register on or before Jan. 1st, 1890, or who have obtained a registrable qualification on or before that date; (*β*) candidates who have for a period of three years held the position of medical officer of health to any county, or to any urban district of more than 20,000 inhabitants, or to any entire rural sanitary district. The examination is in two parts. The first part will

[1] The regulations were last settled on June 9th, 1896, and came into operation on Jan. 1st, 1897.

Digitized by Google

comprise Physics and Chemistry; the principles of chemistry and methods of analysis, with especial reference to analyses of air, water, and food; application of the microscope, including the investigation of micro-organisms; the laws of heat and the principles of pneumatics, hydrostatics, and hydraulics, with especial reference to ventilation, water-supply, drainage, construction of dwellings, disposal of sewage and refuse, and sanitary engineering in general; meteorology in relation to health; sources of water-supply; and statistical methods in their application to public health. The second part will comprise Laws and Statutes relating to public health; origin, propagation, pathology, and prevention of epidemic and infectious diseases, including those diseases of animals that are transmissible to man; effects of overcrowding, vitiated air, impure water, and bad or insufficient food; unhealthy occupations and the diseases to which they give rise; water-supply and drainage in reference to health; nuisances injurious to health: distribution of diseases within the United Kingdom, and effects of soil, season, and climate. The following is a list of Colleges and Schools of Medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the State Medicine Syndicate: The Chemical and Pathological Laboratories, Cambridge; the University of Edinburgh; the London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London: University College, London; the Army Medical School, Netley; Owens College, Manchester; the University of Durham Medical School, Newcastle-on-Tyne; Mason College, Birmingham; University College, and Southern Hospital School, Liverpool; St. Mary's Hospital Medical College; Charing-cross Hospital College; Westminster Hospital; University College, Bristol; and Yorkshire College, Leeds. The examination in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work and one day to oral and practical examination in, and reporting on, subjects connected with out-door sanitary work. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which concern the public health. Every candidate will be required to pay a fee of £6 6*s*. before admission or readmission to *either part* of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination should be addressed to Dr. Anningson, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination in October next must send in their applications on forms supplied for the purpose and transmit the fees to J. W. Clark, M.A., Registrary, University of Cambridge, on or before Sept. 17th. Cheques should be crossed "Barclay and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. The applications of candidates whose names have not been on the Medical Register for three years should be accompanied by a certificate of birth or other proof of age.

University of Oxford (Diploma in Public Health).[2]—An examination, open to all registered medical practitioners, conducted partly in writing, partly *viva voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Pathology, with special relation to Infectious Diseases, the Laws relating to Public Health, Sanitary Engineering, Vital Statistics,. The fee for admission to the examination is £10. Candidates (*a*) must have spent after registration a period of at least six months studying in a public health laboratory approved by the Board of the Faculty of Medicine. Candidates must also (*b*) have had their names on the Medical Register of the United Kingdom for a period of at least twelve months; (*c*) have spent after registration a period of study of not less than six months in all, under the medical officer of health of a county or of a city or town containing at least 50,000 inhabitants, or under two or more such medical officers of health. Certificates of proficiency are granted to those who pass this examination.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B. Hy.) must be at least twenty-two years of age and registered, and before presenting themselves for examination must have been for at least twelve months graduates in Medicine of a recognised university. They shall spend six months at Newcastle-upon-Tyne studying Public Health, Comparative Pathology, Practical Bacteriology, Out-door Sanitary Work, Infectious Diseases, Sanitary and Practical Chemistry. They have to pass an examination in Sanitary Chemistry, Physics, Sanitary Legislation, Comparative Pathology, Vital Statistics, Nosology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas, and for the degree £6 6*s*. Candidates for the degree of Doctor in Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a Medical Officer of Health, and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5, and for the degree £6 6*s*. The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University, and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and diploma in Public Health is ten guineas.

Victoria University.—An examination in Public Health is held yearly under the following regulations: The examination is in two parts, and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health in a college of the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University, the courses including Chemistry as applied to Public Health, Bacteriology, and the Pathology of those diseases of animals which are communicable from animals to man; of having attended for three months the clinical practice of a hospital for infectious diseases; of having practically studied the duties of out-door sanitary work for not less than six months under the Medical Officer of Health of a county or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5*s*., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin on the third Monday in July each year.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health: Section 1: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £5 5*s*. A candidate intending to present himself must give fourteen days' written notice to the Secretary, at the Examination Hall, Thames Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I. of the examination on producing evidence of being at least twenty-three years of age, and to Part II. on producing evidence of being at least twenty-four years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least twelve months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least twenty-three years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having, during a period of six months

after obtaining a registrable qualification, either practically studied the duties of out-door sanitary work under the medical officer of health of a county or large urban district or else held appointment as medical officer of health under conditions not requiring the possession of a special Sanitary diploma; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, either before or after obtaining his registrable qualification in Medicine, Surgery, and Midwifery (this certificate is not required in the case of a candidate who produces evidence that he has commenced special study of Sanitary Science before Jan. 1st, 1894); and (3) of being at least twenty-four years of age.

King's College, London.—The necessary Laboratory Instruction to comply with the regulations of the various Universities and other Medical Licensing Bodies will be given by Professor William R. Smith, M.D., D.Sc., and Professor Edgar M. Crookshank, M.B. Lond. The syllabus includes Physics, Chemistry, Microscopy; Parasites and other Organisms Infesting Food-stuff or the Human Body; Bacteriology, including the Cultivation and Recognition of Micro-organisms. The course will last six months, four months of which will be spent in the Laboratories of Public Health, and two months in the Bacteriological Laboratory. Fee 20 guineas, payable in advance in the College Office. Under the direction of Professor William R. Smith, M.D., D.Sc., and Demonstrator C. G. Moor, M.A., F.C.S., practical instruction will be given in the laboratories in the methods of Analysis of Air, Water, Foods, &c.; Detection of Poisons. Fees, one month, £4 4*s.*; three months, £10 10*s.* The laboratories are also available for original investigations and practical work in Public Health, and are open daily from 9 A.M. to 4 P.M. and on Saturdays to 1 P.M. In Public Health special classes will be held during the winter session by Professor W. R. Smith; fee, £12 12*s.* The Bacteriological Laboratory is open daily for original research under the direction of the professor and demonstrator of Comparative Pathology and Bacteriology. For one month for original research, 3 guineas. For a longer period by arrangement. For one month for private study, with supervision, 4 guineas. For a longer period by arrangement. Practical course for a month, with attendance on lectures, 5 guineas. For a year, 30 guineas. Professor H. G. Seeley, F.R.S., will deliver a course of six lectures on Physiography. For further particulars connected with any of the foregoing classes apply to Professor W. R. Smith, King's College, London.

University College, Bristol.—A course of lectures on the Principles and Practice of Hygiene is given at the College by D. S. Davies, M.D. Lond., D.P.H. Cantab., on Mondays and Fridays, 10–11 A.M., commencing on the first Monday in October. A six months' course of Practical Laboratory Instruction is given at the Western Counties' Laboratory, Park-street, by Mr. F. Wallis Stoddart, commencing on the first Wednesday in October, and including the subjects of Chemistry, Physics, Bacteriology, and Parasites. Demonstrations on the provisions and practical working of the various Acts relating to Public Health and on the Orders, Circulars, and By-laws of the Local Government Board are delivered by Mr. J. C. Heaven on Mondays and Fridays, commencing on the first Monday in October. Gentlemen taking out the course are admitted to practical out-door sanitary work during the session, under the supervision of the Medical Officer of Health for the city and port of Bristol. They are considered as pupil assistants, and are required to carry out diligently such of the duties of medical officers of health as they may be directed to undertake. Facilities are afforded during the course for the study of those diseases of the lower animals which are communicable to man. Fee for the entire course, 20 guineas.

SCOTLAND.

Edinburgh University.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least twenty hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended lectures on Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than eighteen months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of forty lectures at least; one of these courses shall deal with medicine and the other with engineering, each in its relation to public health. They must also give evidence (1) that for six months they have practically studied sanitary work under the medical officer of health of a county or borough or district containing a population of not less than 25,000; (2) that they have had three months' clinical instruction regarding fevers and infectious diseases; and (3) that they have had three months' instruction in mensuration and drawing. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3*s.* for the First and £3 3*s.* for the Second B.Sc. Examinations, and £10 10*s.* for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than twelve months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene in a laboratory approved of by the University, together with having for a like period after graduation practically and daily studied the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district, or of having himself held appointment as Medical Officer of Health. He must also have regularly attended for six months the wards of a general fever hospital containing not less than fifty beds. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send in their names, with the necessary fee, to the Secretary of the Medical Faculty before the first day of the month in which the examination takes place. The fee for the examination is £5 5*s.* The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period or they may enter for Part I. at one period and for Part II. at another and subsequent period.

The Royal Colleges of Surgeons and Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—All candidates for the diploma in Public Health must have been qualified for at least one year. Those qualified before 1890 and also those who have held the position of Medical Officer of Health to a county or to an urban district of more than 20,000 inhabitants, or an entire rural sanitary district, do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised public health laboratory or laboratories, and must have studied for six months the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district, or must themselves have held an appointment as Medical Officer of Health under conditions not requiring the possession of a sanitary diploma. It is also recommended where possible to take out a course of instruction in the diseases of animals transmissible to man.

There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes (*a*) Laboratory Work, (*b*) Chemistry,

Digitized by Google

(*c*) Physics, and (*d*) Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of £3 3*s*. is payable by rejected candidates to either examination. The examination is held twice yearly in May and October. The published regulations provide detailed synopsis of the subjects of examination and give lists of books from which to select. The Registrar for Edinburgh is Mr. James Robertson, Solicitor, 48, George-square; and for Glasgow Mr. Alexander Duncan, LL.D., 242, St. Vincent-street.

IRELAND.

Royal University of Ireland.—This University grants a diploma in Sanitary Science. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of twelve months from the time of obtaining the first registrable qualification; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2, at least one month previously to the examination. Candidates are required to produce a certificate of having, after obtaining the degree of M.B., B.Ch., B.A.O., attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district.

University of Dublin.—The Diploma in State Medicine is conferred, after examination, on the following conditions:—The candidate must be a Doctor in Medicine or a graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least twelve months before the examination. The candidate must have completed, subsequently to registration, six months' practical instruction in a laboratory approved by the University and also have studied practically out-door sanitary work for six months, under an approved officer of health. The subjects of examination will be—(*a*) State Medicine and Hygiene, including causation and prevention of disease, contagion in different diseases, morbid diathesis, congenital diseases and malformations, diseases of animals in relation to the health of man, diseases of the vegetable kingdom, famine diseases, causes of origin and spread of epidemics, principles of bacteriology, quarantine, disinfection, &c.; (*b*) Chemistry, including air, water, and articles of food and drink, and their chemical and microscopical examination and analysis, the detection of common poisons and recognition of injurious pigments, &c.; (*c*) Physics and Meteorology; (*d*) Engineering; (*e*) Morbid Anatomy; (*f*) Vital Statistics; (*g*) Medical Jurisprudence; and (*h*) Practical Sanitary Engineering, Epidemiology, and Duties of a Public Health Officer.

Royal College of Physicians and Royal College of Surgeons in Ireland.—Stated examinations for the diploma in State Medicine are held in the months of February, May, and November. A special examination for the diploma can be (except during the months of August and September) obtained on payment of £5 5*s*., in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination. Every candidate for the diploma in State Medicine must be a registered medical practitioner. (Candidates registered or entitled to be registered prior to January, 1890, are exempt from the rules as to study.) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months either practically study out-door sanitary work under a Medical Officer of Health or himself hold an appointment of Medical Officer of Health under conditions not requiring the possession of a special sanitary diploma. Candidates are examined on four days commencing on the first Tuesday of February, May, and November, and shall as an additional requirement attend a hospital for infectious diseases. Each candidate must return his name to the secretary of the committee of management under the conjoint scheme three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10*s*. The examination for the diploma in State Medicine comprises the following subjects:—State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Law and Bacteriology. For further particulars apply to the Secretary, Committee of Management Office, Royal College of Physicians, Dublin.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it costs but little trouble to pass the special examinations. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than three years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). In the case of qualified surgeons two years will suffice. The Dental Schools in London are the Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals. A convenient arrangement by which the M.R.C.S., L.R.C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed the student should become apprenticed to a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to the date of registration as a dental student.) During his apprenticeship the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital. (The foregoing constituting the First Examination.) Having entered the hospital the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology. At the completion of his second year of study the Dental Examination should be passed. The student should then devote his time to general studies and pass the Third Examination. When time permits it is advisable to attend the general hospital only until after the First and Second Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L.D.S. diploma. The best course, however, is to entirely finish the curriculum for the M.R.C.S. and L.R.C.P. and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Students who commenced their professional education by apprenticeship to dentists entitled to be registered or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory), are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies and of having received three years'

Digitized by Google

instruction in Mechanical Dentistry from a registered practitioner. One year's *bonâ fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as of the four years of professional study. The three years of instruction in Mechanical Dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to register and no foreign qualifications are admitted. Formerly exception was made with regard to the Universities of Harvard and Michigan.
